THE

GARDENER'S AND BOTANIST'S DICTIONARY;

CONTAINING

THE BEST AND NEWEST METHODS OF CULTIVATING AND IMPROVING THE

KITCHEN, FRUIT, AND FLOWER GARDEN, AND NURSERY;

OF PERFORMING THE

PRACTICAL PARTS OF AGRICULTURE;

OF MANAGING VINEYARDS,

AND

OF PROPAGATING ALL SORTS OF TIMBER TREES.

BY THE LATE

PHILIP MILLER, F.R.S.

GARDENER TO THE WORSHIPFUL COMPANY OF APOTHECARIES AT THEIR BOTANIC GARDEN IN CHELSEA, AND MEMBER OF THE BOTANIC ACADEMY AT FLORENCE.

TO WHICH ARE NOW FIRST ADDED,

A COMPLETE

ENUMERATION AND DESCRIPTION OF ALL PLANTS HITHERTO KNOWN,

WITH THEIR

GENERIC AND SPECIFIC CHARACTERS,

PLACES OF GROWTH, TIMES OF FLOWERING, AND USES BOTH MEDICINAL AND ECONOMICAL.

THE WHOLE CORRECTED AND NEWLY ARRANGED,

WITH THE ADDITION OF ALL THE MODERN IMPROVEMENTS IN LANDSCAPE GARDENING, AND IN THE CULTURE OF TREES, PLANTS, AND FRUITS,

PARTICULARLY IN THE VARIOUS KINDS OF HOT HOUSES AND FORCING FRAMES:

WITH PLATES EXPLANATORY BOTH OF THEM, AND THE PRINCIPLES OF BOTANY.

BY

THOMAS MARTYN, B.D. F.R.S.

REGIUS PROFESSOR OF BOTANY IN THE UNIVERSITY OF CAMBRIDGE.

IN TWO VOLUMES.

VOL. II. PART II. Q—Z.

QUALEA.

Lin. gen. Schreb. n. 12. *Juſſ.* 424. *Aubl. guian. t.* 1.

Claſſ. 1. Monandria Monogynia.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, deeply four-parted: ſegments ovate, coriaceous, concave, unequal, the two lower larger, gaping.

COR. *Petals* two, unequal, inſerted into the calyx: *upper* erect, roundiſh, emarginate, ending at the baſe in a horn-ſhaped, ſhort, blunt *Nectary*, prominent between the upper ſegments of the calyx: *lower* larger, bending down.

STAM. *Filament* one, ſhort, aſcending, inſerted between the lower petal and the germ. *Anther* oblong, grooved, recurved.

PIST. *Germ* globular. *Style* filiform, aſcending, the length of the ſtamen. *Stigma* blunt.

PER. Berry? one-celled.

SEEDS very many, neſtling in the pulp.

OBS. *The corolla has the form of a bilabiate one. The genus is allied to* Cucullaria.

QUA

ESSENTIAL CHARACTER.

Cal. four-parted. *Cor.* two-petalled. *Berry.*

SPECIES.

1. Qualea roſea.
   Lin. ſpec. ed. Willd. 18. *Aubl. guian.* 1. 5. *t.* 1.
   Lower petal blunt, leaves acuminate.
2. Qualea cœrulea.
   Lin. ſpec. ed. Willd. 18. *Aubl. guian.* 1. 7. *t.* 2.
   Petals emarginate, leaves acute.

DESCRIPTIONS, *&c.*

1. This is a tree attaining the height of ſixty feet and more; and two feet in diameter: the bark is wrinkled, and the wood reddiſh and compact: at the top it has large branches, ſome growing right up, others horizontal, ſpreading wide in all directions: the twigs are oppoſite. Leaves ſmooth, ſhining, firm, entire, oval: from the midrib ſpring many lateral nerves, ſimple and parallel. Petiole cylindrical, nine lines in length, accompanied at its origin by two deciduous ſtipules. Flowers in terminating panicles; the branches and branchlets oppoſite. Bractes in pairs, ſmall, deciduous, at the baſe of the branchlets. The flowers ſmell very agreeably. This tree is called *Laba-Laba* by the Galibis. It grows in the foreſts of

184998

Digitized by Google

Guiana, which extend to the bank of the river Sinemari, twelve leagues from its mouth.

2. This alſo is a tree from ſixty to eighty feet in height, and three feet in diameter, with a bark and wood like the former. The branches and branchlets alſo are the ſame. The leaves are ſhort, in moſt reſpects like the other, but terminating only in a ſhort point. The petiole is ſhort. The flowers are in large panicles, with ſome of the branches alternate. The upper petal is aſh-coloured without, and blueiſh within; the lower is blue, except towards the claw, where it is yellow marked with black: whereas in the other ſpecies the upper petal is white on the outſide, and roſe-coloured within; the lower in opening is reddiſh, but when expanded becomes white towards the claw, the reſt yellow. The flowers have a ſweet pleaſant odour. This tree has the name of *Qualé* among the Galibis, whence the generic name. It is found in the ſame country, but higher up the river, namely forty leagues from its mouth[l].

Nat. order of *Gruinales*. *Magnoliæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* five-leaved, very ſhort: *leaflets* ovate, permanent.

COR. *Petals* five, lanceolate, elongated, ſeſſile, equal. *Nectary* of five ovate villoſe ſcales, inſerted into the interior baſe of the filaments.

STAM. *Filaments* ten, filiform, equal, the length of the corolla. *Anthers* oblong, incumbent.

PIST. *Receptacle* fleſhy, orbicular, elevated, wider than the germ. *Germ* ovate, compoſed of five. *Style* filiform, the length of the ſtamens. *Stigma* ſimple.

PER. five, lateral, diſtant, inſerted into the fleſhy orbicular receptacle, ovate, obtuſe, two-valved.

SEEDS ſolitary, globular.

ESSENTIAL CHARACTER.

Cal. five-leaved. *Petals* five. *Nect.* five-leaved. *Peric.* five, diſtant, each having one ſeed.

SPECIES.

1. Quaſſia amara. *Bitter Quaſſia.*

Lin. ſpec. 553. 1679. *ſyſt. ed.* 13. 333. *ed.* 14. 401. *Reich.* 275. *mat. med.* 114. *Woodv. med. bot.* 215. *t.* 77. *Amæn. acad.* 6. 421. *t.* 429. *Suppl.* 235. *Patris in Roz. obſ. t.* 9. *p.* 140. *Febr. t.* 2. *Plenck ic.* 333.

Flowers hermaphrodite, leaves unequally pinnate, leaflets oppoſite ſeſſile, petiole jointed winged, flowers in racemes.

2. Quaſſia Simaruba. *Simaruba Quaſſia.*

Lin. ſyſt. 401. *ſuppl.* 234. *Gærtn. fruct.* 1. 340. *Woodv. med. bot.* 211. *t.* 76. *f.* *Lond. med. journ.* 11. 1. *Tranſ. edinb.* 2.

Simaruba amara. *Aubl. guian.* 859. *t.* 331. 332.

Flowers monoecous, leaves abruptly pinnate, leaflets alternate ſubpetioled, petiole naked, flowers in panicles.

3. Quaſſia excelſa. *Lofty Quaſſia.*

Swartz prodr. 67.

Flowers hermaphrodite five-ſtamened panicled, leaves unequally pinnate, leaflets oppoſite petioled, petiole naked.

DESCRIPTIONS, *&c.*

1. This is a lofty tree, with many ſtrong branches; the wood white and light, the bark thin, and of a gray colour. Leaves alternate, interruptedly pinnate, conſiſting of two pairs of oppoſite leaflets at the joints of the petiole, and an odd one at the end. Leaflets elliptic, entire, veined, ſmooth, acuminate at both ends, ſeſſile, deep green on the upper, paler on the under ſurface. Common petiole two-jointed, and winged like the orange with a leafy membrane gradually ſpreading to the joints. The flowers terminate the branches in elongated racemes or ſpikes, directed one way, all hermaphrodite, of a bright red colour. Bractes lanceolate or linear, coloured, alternate. It is eaſily known by its leaves, which are very different from all others.

Native of South America, particularly of Surinam; and alſo of ſome of the Weſt India iſlands[m].

The figure given in the Amoenitates Academicæ is not a juſt one, the flowers only, as the younger Linneus has obſerved, being right, but the branch with leaves belonging to another plant, hence the figures of Buchoz, Lettſom, &c. copied from this, are inaccurate: thoſe of Patris and Woodville are right.

The root, wood, bark, and indeed all the parts of this tree are intenſely bitter. Linneus ſays that the wood of the root is a noble remedy, but that the wood of the ſmall branches which has ſince been ſubſtituted for it is good for nothing. The wood of both is now thought to be leſs intenſely bitter than the bark, which is at preſent regarded as the moſt powerful medicine.

Quaſſia has no ſenſible odour; its taſte is that of a pure bitter, more intenſe and durable than of almoſt any other known ſubſtance; it imparts its virtues more completely to watery than ſpirituous menſtrua, and its infuſions are not blackened by the addition of martial vitriol.

The negro Quaſſi, Quaſs, or as it is written by Fermin Coiſſi, is ſaid to have employed it with uncommon ſucceſs, as a ſecret remedy in the malignant endemic fevers, which frequently prevailed at Surinam. For a valuable conſideration this ſecret was diſcloſed to Daniel Rolander, a Swede, who brought ſpecimens of the wood to Stockholm, in the year 1756; and ſince that time the effects of this drug have been generally tried in Europe. The medicinal qualities aſcribed to Quaſſia are thoſe of a tonic, ſtomachic, antiſeptic and febrifuge.

Dr. Cullen believes Quaſſia to be an exeellent bitter, and thinks it will do all that a ſimple bitter can do, but no more: he aſcribes the extraordinary commendations which are given it, to the partiality ſo often ſhown to new medicines.

It may be given in infuſion, or in pills made from the watery extract; the former is generally preferred in the proportion of three or four drams of the wood to twelve ounces of water[n].

It is ſaid that conſiderable quantities of this drug are uſed by the brewers inſtead of hops.

2. This tree grows to a conſiderable height and thickneſs, with alternate ſpreading branches: the bark on the trunk of old trees is black and a little furrowed, but that of younger trees is ſmooth, gray, and here and there marked with broad yellow ſpots: the wood is hard, white, and without any remarkable taſte. Leaves numerous, alternate, compoſed of ſeveral leaflets (from two on each ſide to nine) oblong or nearly elliptic, ſharp at the end, ſmooth above, and of a deep green colour, beneath whitiſh, placed alternately on very ſhort foot-ſtalks. Flowers on branched ſpikes, or long wide axillary panicles, of a yellow colour.

According to Linneus and others, the male and female flowers are mixed in the ſame panicle; but Dr. Wright ſays that the female flower is never found on the ſame tree with the male, in Jamaica. The ſmall calyx is cut into five obtuſe erect ſegments in both; the five petals are ſeſſile, equal, lanceolate, bent outwards, three times the length of the calyx, into which they are inſerted. Nectary compoſed of ten roundiſh or ovate villoſe ſcales, inſerted in a ring at the interior baſe of the filaments. Receptacle marked with ten grooves. The male flowers have an abortive germ, depreſſed, five-ſtreaked, covered by the nectaries, but without any ſtyle or ſtigma. The fertile flowers have no ſtamens, but five roundiſh germs adhering together, with a cylindrical erect ſtyle, about the length of the corolla, divided at the top into five recurved permanent ſtigmas. The fruit is ovate, black, ſmooth, pulpy, compoſed of five drupes, but

[l] Aublet.

ſeldom more than two or three arrive at maturity: each of theſe contains an oblong pointed nut with a flattiſh kernel*. Gærtner names them berries, which he deſcribes as five in number, from upright ſpreading, ovate, convex on one ſide, keeled with a blunt angle on the other, black, ſmooth, one-celled; the pulp fungoſe, thick, hardiſh; the cell inveſted with a cartilaginous membrane. The common receptacle ſmall, fleſhy, ſubpentangular: the proper receptacle, a thin membranaceous *lacinula*, ſpringing from the internal angle of the cell, and inſerted into the ſide of the ſeed below the tip. Seed ovate-oblong, very ſlightly compreſſed above, thickened and rounded below, of a pale colour.—Gærtner remarks, that the berries which he examined were very dark ſmooth and ſhining, whereas thoſe figured by Aublet have branched veſſels on the outſide of them: and that this pericarp is between a berry and a capſule, ſeeming to open ſpontaneouſly inwards when ripe.

Simaruba is a native of South America and the iſlands of the Weſt Indies. In Jamaica it is known by the names of Mountain Damſon, Bitter Damſon and Stave-wood. Although the bark was firſt imported into Europe in 1713, it is but a few years ſince this plant was botanically aſcertained. Dr. Wright ſays, that in 1773, ſpecimens of the fructification were ſent from Jamaica in ſpirits to Dr. Hope at Edinburgh, with ſome dried bark from the roots: and that the following year ſpecimens were alſo tranſmitted to Dr. John Fothergill of London, who ſent them to Linnæus at Upſal. By the aſſiſtance of Mr. Alexander Anderſon, it was introduced into the royal garden at Kew in 1787. The bark was firſt ſent from Guiana to France in 1713 to the Count de Ponrchartrain, then ſecretary of ſtate, as a remedy of great efficacy in dyſentery. In 1718 and 1723 an epidemic flux prevailed very generally in France, which reſiſted all the medicines uſually employed in ſuch caſes; under theſe circumſtances, recourſe was had to *cortex Simarubæ*, which proved remarkably ſucceſsful, and firſt eſtabliſhed its medical character in Europe.

This drug is the bark of the roots of this tree; which is rough, ſcaly and warted: the inſide, when freſh, is a full yellow, but when dry paler: it has little ſmell; and the taſte is bitter, but not diſagreeable. Macerated in water, or in rectified ſpirit, it quickly impregnates them with its bitterneſs, and with a yellow tincture: the cold infuſion in water is rather ſtronger in taſte than the decoction; which laſt grows turbid and of a reddiſh brown as it cools.

Dr. Wright ſays, moſt authors who have written on the Simaruba agree, that in fluxes it reſtores the loſt tone of the inteſtines, allays their ſpaſmodic motions, promotes the ſecretions by urine and perſpiration, removes the lowneſs of ſpirits attending dyſenteries, and diſpoſes the patient to ſleep*; the gripes and teneſmus are taken off, and the ſtools are changed to their natural colour and conſiſtence. In a moderate doſe it occaſions no diſturbance or uneaſineſs, but in large doſes it produces ſickneſs at the ſtomach and vomiting. Modern phyſicians have found this medicine ſucceſsful only in the third ſtage of dyſentery, where there is no fever, where the ſtomach is not hurt, and where the gripes and teneſmus are only continued by a weakneſs in the bowels: but Dr. Wright is convinced by the experience of himſelf and many friends, of the efficacy of this medicine, and hopes the Simaruba bark will ſoon be in more general uſe.

On the other hand Dr. Cullen cannot perceive any thing in this bark but that of a ſimple bitter; and ſays that the virtues aſcribed to it in dyſentery have not been confirmed by his experience, or that of other practitioners in Scotland; and that in dyſentery he has found an infuſion of chamomile flowers a more uſeful remedy.

Dr. Wright recommends two drams of the bark to be boiled in twenty-four ounces of water to twelve, the decoction is then to be ſtrained and divided into three equal parts, the whole of which is to be taken in twenty-four hours; and when the ſtomach is reconciled to this medicine, the quantity of the bark may be increaſed to three drams. To this decoction ſome join aromatics; others a few drops of laudanum to each doſe†.

3. Obſerved by Swartz in Jamaica.

Leaves ſinuate-pinnatifid pubeſcent underneath, ſegments ſharpiſh, raments axillary filiform, calyxes echinate-ramentaceous.

DESCRIPTIONS, *&c.*

1. the Willow-leaved Oak grows naturally in North America, where they diſtinguiſh two ſorts; one of them (β) is called the Highland Willow Oak, and grows upon poor dry land; the leaves are of a pale green and entire, ſhaped like thoſe of the Willow tree. The acorns are very ſmall, but have pretty large cups.

The other grows in low moiſt land, and riſes to a much greater height; the leaves are larger and narrower, but the acorns are of the ſame ſize and ſhape. Their difference is probably owing to the ſoil in which they grow.

[The latter becomes a large timber tree, and there are ſaid to be ſeveral varieties of it.—It was cultivated here in 1724, as appears from Furber's catalogue. It flowers in may and june[q].

2. This is ſo named from its having been found by Rumphius in the Molucca iſlands.

3. Branches by twos or threes, wrinkled, knobbed, from upright ſpreading. Leaves alternate, petioled, attenuated at the baſe, cuſped, quite entire, parallel-nerved, ſmooth on both ſides, ſhining above, yellowiſh underneath. Spikes of flowers terminating, ſolitary or two or three together, tomentoſe.

4. Branches knobbed, dotted with white, aſh-coloured, ſmooth, tomentoſe at the end. Leaves alternate, petioled, rounded at the baſe, entire, parallel-nerved, in their advanced ſtate ſmooth, but ferruginous-tomentoſe underneath when young. Spikes of flowers axillary, ferruginous-tomentoſe.

5. This is a very large tree. Branches and branchlets ſubumbelled, round, ſmooth, with raiſed white dots, purple, erect. Leaves alternate, on ſhort petioles, attenuated at the baſe, entire, toothed or ſerrate from the middle to the tip, cuſped, above ſmooth and green, underneath mealy-white, parallel-nerved, from two to three inches long, and near two inches wide. Flowers axillary. The neſt of an inſect frequently adheres to the branches. It differs from Q. Ilex and Suber in having the leaves wider, obovate, cuſped, attenuated and entire at the baſe, glaucous or mealy underneath and not tomentoſe, parallel-nerved.

6. Branches ſtriated, ſmooth, ſpreading. Leaves alternate, petioled, rounded at the baſe, having unarmed ſerratures from the middle to the tip, parallel-nerved, very ſmooth on both ſides, an inch long. Female flowers ſcattered on the branchlets, ſolitary, ſubſeſſile. Calyxes echinate, the ſize of a hazel nut. The acorns are ſaid to be eaten both raw and dreſſed. It differs from Q. Ilex and Suber in having ſmooth leaves—from Q. coccifera in having cuſped leaves with unarmed ſerratures—from Q. glauca in having the leaves ovate, quite ſmooth, and ſmaller, with echinate calyxes.

7. Branches and branchlets alternate, ſmooth, aſh-coloured, knobbed, muricated with white dots, ſpreading. Leaves alternate, acuminate, the whole edge ſharply and equally ſerrate, green above, paler underneath, parallel-nerved, when young ſilky-tomentoſe, but when more advanced very finely villoſe, unequal, from an inch to a hand in length.

8. Branches and branchlets thick, wrinkled, grooved, muricated with dots and little knobs, the upper ones tomentoſe, erect. Leaves aggregate at the ends of the branchlets, on very ſhort petioles, unarmed, parallel-nerved, villoſe above, ſoft, two inches long. The ſix laſt ſpecies were obſerved by Thunberg in Japan[r].]

9. Of the Ilex or evergreen Oak there are ſeveral varieties, differing greatly in the ſize and ſhape of their leaves; but theſe will all ariſe from acorns of the ſame tree; nay the lower and upper branches have very frequently leaves very different in ſize and ſhape, thoſe on the lower branches being much broader, rounder, and their edges indented and ſet with prickles; but thoſe on the upper long, narrow, and entire. The leaves of the Ilex are from three to four inches long, and an inch broad near the baſe, gradually leſſening to a point; they are of a lucid green on

[q] Hort. kew. [r] Thunb. jap.

their

Digitized by Google

their upper ſide, but whitiſh and downy on their under, ſtand upon pretty long foot-ſtalks, and do not fall till they are thruſt off by young leaves in the ſpring. The acorns are ſmaller than thoſe of the common Oak, but of the ſame ſhape.

[Scopoli remarks, that the leaves are faithleſs ſpecific characters in this genus, and that the bark, cups of the fruits, and galls, afford more certain diſtinctions.

Native of the South of Europe, Cochinchina and Barbary.—It is a ſtranger in England, ſays Gerarde, (1597) notwithſtanding there is here and there a tree thereof, that hath been procured from beyond the ſeas; one groweth in his Majeſties garden of Whitehall, near to the gate that leadeth into the ſtreet. Our old authors name it the Holm Oak, an appellation correſponding better with the next ſpecies, which has leaves much reſembling the Holly or Holm. In French it is *le Chêne verd:* in Italian *Elice*; in Spaniſh *Enzina.*

The wood, ſays Evelyn, is ſerviceable for ſtocks of tools, mallet-heads, mall-balls, chairs, axle-trees, wedges, beetles, pins, and paliſadoes in fortifications: it ſupplies almoſt all Spain with the beſt and moſt laſting charcoal.—Mr. Boutcher affirms that theſe trees ſoon make warm and lofty hedges, forty or fifty feet high; but that they ſhould not be planted near the houſe or in the gardens, becauſe they make a great litter in april and may, when they caſt their leaves.

Mr. Bradley ſays, that the Ilex produces admirable timber, particularly valuable for knee timber, being much tougher than Engliſh Oak; that many ſhip's lading of it have been brought to England; that it is of quick growth; that Robert Balle, Eſq. raiſed ſome thouſands of theſe trees from acorns at Mamhead in Devonſhire, ſome of which, in thirty years, have grown to a conſiderable ſize; and that within the compaſs of ſix years (1724) many millions of them have been raiſed in England, from acorns brought from Italy and Virginia, as well as great numbers of Cork-trees *. The latter were killed by the froſt; but what is become of the millions of Ilexes?

10. This is hardly a diſtinct ſpecies from the common Evergreen Oak [t]. It is a native of the South of France; and appears to have been cultivated here in 1730. It flowers in june [t].

11. This tree is allied to the Ilex; but the leaves are tomentoſe and white underneath, and the acorn is almoſt twice as long, with a ſweet pleaſant taſte; it differs alſo in height and habit from the Ilex, and from the Cork-tree eſpecially in not having a fungoſe bark. It varies by ſoil and age: in ſome trees the leaves being ſmall and orbicular; in others elliptic; in others again lanceolate and acute. It ſeems to be the ſame with Ilex major of Cluſius. (hiſt. 22.)

Native of Barbary, about Algier, Belide, Maſcar, Themſen, &c. and of Spain, if it be Cluſius's tree. The acorns are eaten both raw and roaſted. The wood being compact and very hard is uſed for many purpoſes.

This very uſeful tree, according to Monſ. Desfontaines, was not unknown to the ancients: for Pliny ſays—" glandes opes eſſe nunc quoque multarum " gentium etiam pace gaudentium conſtat, nec non & " inopia frugum arefactis molitur farina, ſpiſſaturque " in panis uſum." *L.* 16. *c.* 5 [u].

12. This is a large tree, with aſcending branches. The wood is very hard, heavy, and brown. Leaves ſomewhat acuminate, ſmooth, hard, alternate, petioled. Both male and female flowers are ſeſſile, on long, linear, terminating aments: the former have five ſtamens; the latter three ſimple ſeſſile ſtigmas. Fruit ſomewhat woody, turbinate, truncate, three-celled, one-ſeeded, covered up to the ſhoulders with a thick rough cup, regularly marked with polyhedrous ſegments.—Native of high woods both in China and Cochinchina.

13. This alſo is a high tree with aſcending branches. Leaves acuminate, ſmooth on both ſides, petioled, ſcattered. Male flowers on linear aments, heaped, erect, terminating: females on the ſame ament, but lower and peduncled. Fruit oblong-ovate, acuminate, ſmooth, rufous; with the cup permanent, hollow within like a diſh, engraved on the outſide with five parallel circles.—Native of high woods in Cochinchina.

Though this ſpecies ſeems to reſemble Q. molucca in the leaves, yet it is very different in the curvature of them, and in the cup.

Both ſpecies, as well as the common Ilex, afford excellent timber for ſhip-building, and all domeſtic and rural purpoſes, but *Q. cornea* is ſuperior to the others for bearing great weights [x].]

14. Of the Cork Tree there are two or three varieties; one with a broad leaf, a ſecond with a narrow leaf, both evergreen; and one or two which caſt their leaves in autumn; but the broad-leaved evergreen is the moſt common. The leaves of this are entire, about two inches long, and an inch and quarter broad, with a little down on their under ſides, on very ſhort foot-ſtalks: theſe leaves continue green through the winter till the middle of may; when they generally fall off juſt before the new leaves come out; ſo that the trees are often almoſt bare for a ſhort time. The acorns are very like thoſe of the common Oak.

The exterior bark is the cork, which is taken from the tree every eight or ten years; but there is an interior bark which nouriſhes them, ſo that ſtripping off the outer bark is ſo far from injuring the trees, that it is neceſſary to continue them; for when the bark is not taken off, they ſeldom laſt longer than fifty or ſixty years in health; whereas trees which are barked every eight or ten years, will live 150 years or more. The bark of a young tree is porous and good for little; however it is neceſſary to take it off when the trees are twelve or fifteen years old, for without this the bark will never be good: after eight or ten years, the bark will be fit to take off again; but this ſecond peeling is of little uſe: at the third peeling the bark will be in perfection, and will continue ſo for 150 years, for the beſt cork is taken from old trees. The time for ſtripping the bark is in july, when the ſecond ſap flows plentifully: the operation is performed with an inſtrument like that which is uſed for diſbarking the Oak.

[Native of the South of Europe, Barbary, &c. Pliny ſays that there were no Cork trees in France or Italy in his time. At preſent there are conſiderable woods of them in the South of France, between Rome and Naples, between Piſa and Leghorn, where all the underwood is Myrtle, &c. It was cultivated here in 1699 by the Dutcheſs of Beaufort [y]. The tree which I remember to have ſeen in the botanic garden at Chelſea, which was killed in the ſevere winter of 1739-40, muſt at leaſt have been of that age, if not older.

The uſes of Cork, ſays Mr. Evelyn, are well known amongſt us both at ſea and land, for its reſiſting both water and air: the fiſhermen who deal in nets, and all who deal with liquors, cannot be without it. Antient perſons prefer it before leather for the ſoles of their ſhoes, being light, dry and reſiſting moiſture; whence the Germans name it *Pantoffel-holtz* or Slipper-wood; but it was firſt applied to that purpoſe by the Grecian ladies, whence they were called light-footed: from them it is likely the Venetian dames took it up for their monſtrous choppines; affecting or uſurping an artificial eminency above men, which nature has denied them. The poor people in Spain lay broad planks of it by their bed-ſide to tread on; as great perſons uſe Turky and Perſian carpets, to defend them from the floor; and ſometimes they line the walls, and inſide of their houſes built of ſtone, with this bark, which renders them very warm, and corrects the moiſture of the air. Alſo they employ it for bee-hives [z]. For this laſt purpoſe they roll the bark of young trees and of the branches into a cylinder, in Barbary, where this tree abounds [a].

Desfontaines has a ſpecies which he names Q. Pſeudo-

Suber,

Digitized by Google

Suber, from its having a fungoſe bark, but in a leſs degree than in the true Suber. The younger branches are tomentoſe, hoary and ſtriated. Stipules ſubulate, membranaceous, deciduous. Leaves deciduous, ovate-oblong, ſmooth above, pubeſcent underneath, aſh-coloured, acute, ſerrate; the ſerratures ſomewhat remote, longer or ſhorter according to the age of the tree or the ſoil. Fruit on a ſhort peduncle. Cup echinate with ſcales looſiſh at the tip. Nut oblong, ovate, of the ſame ſize as in the Ilex. Leaves in younger trees deeply ſinuate and ſerrate; in older ones ſlightly ſerrate. The flowers come out early in ſpring.—Found about Tlemſen.]

15. The Kermes Oak is of ſmall growth, ſeldom riſing above twelve or fourteen feet high, (about two feet, *Villars*) ſending out branches the whole length on every ſide, ſo as to form a buſhy ſhrub. Leaves armed with prickles like thoſe of the Holly. Acorns ſmaller than thoſe of the common Oak. [The leaves reſemble thoſe of the Ilex; but they are leſs, thinner, and green on both ſides [b].

Native of the South of Europe, the Levant, Barbary, &c. Cultivated in 1683, by Mr. James Sutherland. It flowers in may [c].

From this ſpecies they collect the Kermes or Scarlet Grain, a little red gall, occaſioned by the puncture of an inſect called Coccus ilicis.—With this the antients uſed to dye cloth of a beautiful colour called *coccineus* or *coccus*; being different from the *purpura* of the Phœnicians obtained from the ſhell-fiſh called *Murex*. In courſe of time, the Murex was neglected, and the Kermes was introduced. This ſupported its reputation till the diſcovery of America; when, in turn, it gave place to the *Cochineal*, an inſect found in the Mexican woods, upon the Cactus [d].

According to Belon and Rauwolf, the Kermes is exported from Bagdat to India. Desfontaines relates, that although this tree abounds in Barbary, and bears great quantity of the coccus, yet it is totally neglected by the inhabitants, and the drug purchaſed at a high price from the French merchants, for dying woollen cloth red.

The following account of the Kermes is given by the Rev. Mr. Townſend:

Quercus coccifera, Cuſcoja in Spaniſh, grows about Alicant from twelve inches to two feet in height. The *Grana Kermes* appear on the ſtems or ſmall branches, ſome near the bottom, but moſtly on the upper branches, yet always protected by the leaves, and fixed to the ſtem by a glue, reſembling thin white leather, ſpread over the ſtem, and covering, like the cup of the acorn, a ſegment of the grana. The agglutinating coat may be traced through a ſmall hole into the grana, from whence it proceeds, and where it ſpreads, like the placenta, on the internal ſurface.

The grana are of various ſizes from one eighth to one-fourth of an inch in diameter, perfectly ſpherical, and covered with a white powder, which being rubbed off, the ſurface appears red, ſmooth, and poliſhed. On the ſame ſtem the grana may be obſerved in ſeveral ſtages—as in tough membranes filled with a red juice reſembling blood, but on paper leaving a ſtain as bright and beautiful as the beſt carmine. In the ſecond ſtage, under the firſt coat or pellicle is a thin tough membrane incloſing the eggs, now moſt minute, and ſcarcely to be diſtinguiſhed without the aſſiſtance of a glaſs. Between this membrane and the pellicle is the ſame red liquor, but leſs in quantity. This pellicle is evidently ſeparate from the inner membrane, by what ſeems to be the viſcera and blood-veſſels, but near the hole theſe two coats adhere cloſely together.

The interior membrane is thin, white and tough, with a lunar ſeptum, forming the ovary, which at firſt is very ſmall, and ſcarcely diſcernible, but progreſſively enlarges, till in the third ſtage it occupies the whole ſpace, when the tincturing juice diſappears, and only eggs are to be ſeen, to the number of 1500 or 2000.

It is clear that the grana derive no kind of nouriſhment from the plant on which it is fixed; and from its poſition it ſeems that the little animal chooſes the *Quercus coccifera*, which in its prickly leaf reſembles the Holly, only for the ſake of ſhelter and protection from birds.

Some of the grana being put into a coffee-cup on the 31ſt of may, on june the 12th a multitude of animalcula were diſcovered of a bright red colour, exceedingly minute, running about the cup with aſtoniſhing rapidity, but for ſhort intervals. Some grana, being put into a ſnuff-box, were forgot; at the diſtance of a few weeks, the top was found covered internally with dew, and a multitude of winged inſects, all dead, adhering to it.

Beſides the kermes, there are many large red excreſcences on the Qu. coccifera, ſome formed on the leaf, others on the common peduncle of the amentaceous flowers. Theſe morbid tumours have many perforations, communicating with little cells, which contain each a ſmall white grub. The cell is formed by a ſtrong membrane, but the ſubſtance of the tumor is ſpungy [e].

Desfontaines has a ſpecies which he names *Q. Pſeudo-coccifera*; which has the leaves perennial, ovate or elliptic, ſhining, rigid, ſmooth, on very ſhort petioles, ſlightly ſerrate at the edge, with ſpinuloſe ſerratures. Fruit ſeſſile or on ſhort peduncles. Calyx echinate with rigid ſcales, looſiſh at the tip. Acorn ovate, mucronate.—Native of Algiers and mount Atlas.]

American Oaks.

16. This is called *Live Oak* in North America, where it riſes to the height of forty feet. The grain of the wood is hard, tough and coarſe; the bark is grayiſh; the leaves are about three inches long, and an inch and half broad, entire, of a dark green, thick conſiſtence, and placed on ſhort foot-ſtalks. Acorns ſmall, oblong, with ſhort cups; they are very ſweet, and are eaten by the Indians, who lay them up in ſtore for winter; they alſo draw a very ſweet oil from them, little inferior to that of ſweet Almonds.

[It was cultivated by Mr. Miller in 1739 [f]. Linneus confounded it with the firſt ſpecies.]

17. Of this there ſeem to be two varieties, one of which grows to a much larger tree than the other; but this may be occaſioned by the ſoil, for the largeſt trees grow in rich low lands, where they become bigger than any of the North American Oaks. The wood is not of a very fine grain, but is very ſerviceable; the bark is gray and ſcaly; the leaves are five or ſix inches long, and two inches and a half broad in the middle, indented on the edges with many tranſverſe veins running from the midrib to the borders; they are of a bright green, and ſo nearly reſemble thoſe of the Cheſtnut tree, as ſcarcely to be diſtinguiſhed from it. The acorns are very large, and their cups are ſhort. The leaves of the other variety are not ſo large, nor ſo ſtrongly veined, and the acorns are ſmaller and a little longer.

[The Cheſtnut-leaved Oak was cultivated here in 1730 [g]. The two varieties are diſtinguiſhed by the form of the leaves, which in the one is ovate, in the other oblong. It flowers here in may and june [h].

18. The Water Oak is confounded by Linneus with the Black Oak, but the leaves of this are drawn to a point at the baſe, whereas in that they are cordate. The leaves vary much, but all approach to wedge-ſhaped, as may be ſeen in the four varieties enumerated above. Mr. Miller cultivated it in 1748 [i]: it is omitted in his later editions.]

19. The Black Oak grows on poor land in moſt parts of North America, where it never attains to a large ſize, and the wood is of little value. The bark is of a dark brown colour. The leaves are very broad at the top, where they have two waved indentures, which divide them almoſt into three lobes; they diminiſh gradually to their baſe, where they are narrow; they are ſmooth, of a lucid green, and have

Digitized by Google

ſhort foot-ſtalks. The acorns are ſmaller than thoſe of the common Oak, and have ſhort cups.

[Mr. Bartram mentions ſome gigantic black Oaks in North America, many of which meaſured eight, nine, ten, and eleven feet in diameter five feet above the ground, and aſcending perfectly ſtraight, with a gradual taper, forty or fifty feet to the limbs[k]. The above deſcription therefore of Miller's cannot belong to theſe black Oaks of Bartram's, which he names Q. tinctoria, the bark affording a valuable yellow dye; and ſays they are called black Oaks in Pennſylvania, New Jerſey, New York and New England. Miller's deſcription of the leaves agrees rather with the Water Oak.—According to the Kew catalogue, he cultivated the Black Oak in 1739.]

20. This arrives at a large ſize in North America, where it grows naturally. The bark is ſmooth, of a grayiſh colour, but that of the younger branches is darker. Leaves ſix inches long, two inches and a half broad in the middle, obtuſely ſinuate, each ſinus ending in a briſtly point, bright green, ſtanding upon ſhort foot-ſtalks: the leaves continue their verdure very late in autumn; ſo that unleſs hard froſt comes on early, they do not fall till near Chriſtmas, and do not even change their colour much ſooner. Acorns a little longer than thoſe of the common Oak, but not ſo thick.

[There are ſeveral varieties of the Red Oak. It was cultivated in 1691, by Biſhop Compton at Fulham[l].

21. This, which has been confounded with the preceding, was introduced in 1763, by Mr. Murdock Middleton[m].]

22. The wood of the White Oak is eſteemed preferable in America to any of their other ſorts for building, being much the moſt durable. The bark is grayiſh; the leaves are light green, ſix or ſeven inches long, and four broad; they are regularly cut almoſt to the midrib, and ſtand on ſhort foot-ſtalks. The acorns greatly reſemble thoſe of the common Oak. [It was cultivated here in 1724[n].]

23. The leaves of the Eſculus or Italian Oak are ſmooth and deeply ſinuated; ſome of the ſinuſes are obtuſe, and others end in acute points; they are on very ſhort foot-ſtalks: the branches are covered with a purpliſh bark when young: the acorns are long and ſlender; the cups rough and a little prickly, ſitting cloſe to the branches. Theſe acorns are ſweet, and frequently eaten by the poor in the South of France: in times of ſcarcity they grind them and make bread with the flour. [From this eſculent quality of the fruit, this tree was named by the Latins *Eſculus*. It is probable that the Φηγος of the Greeks is the ſame tree: but the *Fagus* of the Latins is the Beech. Profeſſor John Martyn is of opinion that the Eſculus is our ſeſſile-fruited Oak; this variety having a broad, dark green, firm leaf, not ſo much ſinuated about the edges as that of our firſt variety, agreeing better with the "nemorum Jovi quæ maxima frondet" of Virgil. And it is remarkable that the very expreſſion—

——"Quantum vertice ad auras
"Ætherias, tantum radice ad Tartara tendit,"

which the Poet uſes of the Eſculus in the Georgics, he applies to the Quercus in the fourth Æneid.

This ſpecies is a native of the South of Europe; was cultivated in 1739 by Mr. Miller, and flowers in may[o].

The Romans made their civic crowns, firſt of the Ilex, but afterwards of the Eſculus. "Civica iligno "prima fuit, poſtea magis placuit ex Eſculo Jovi "ſacra[p]."

The Eſculus alſo furniſhed a wreath of honour in the games.

"His juvenum quicunque manu, pedibuſve, rotave
"Vicerat, *eſculeæ* capiebat frondis honorem[q]."

24. The Common Oak, as is well known, attains a very great ſize, but ſlowly. In woods it riſes to a

[k] Travels, p. 37. [l] Hort. kew. from Plukenet. [m] Idem. [n] Idem. from Furber's catalogue. [o] Idem. [p] Pliny. [q] Ovid. metam. 1. f. 9.

very conſiderable height, but ſingly it is rather a ſpreading tree, ſending off horizontally immenſe branches, which divide and ſubdivide very much. The trunk is covered with a very rugged brown bark. Leaves alternate, oblong, blunt and broader towards the end, the edges deeply ſinuate, forming obtuſe or rounded lobes, dark green and ſhining above, paler underneath and finely netted, five inches or more in length, two inches and a half in breadth: they are deciduous, but often remain on the tree till the new buds are ready to burſt. The male flowers come out on aments in bundles, from the buds, alternately and ſingly from the axils of the leaves; they are pendulous, cylindrical, a little above three inches long, and two lines wide, conſiſting of yellow, ſhort, roundiſh, ſcattered bundles of anthers, the upper ones nearer, the lower farther diſtant from each other: a ſhort membranaceous toothletted (ſix to nine-toothed) calyx collects the globules of (ſix to nine) anthers. Above the males the aments of female flowers come out, each compoſed of three or four ſmall reddiſh florets placed alternately, having at the baſe little reddiſh ſcales, (involucre) which afterwards become the cup and form the rugged external ſurface of it: there are three reddiſh ſtyles, connected at the baſe, ſtanding out beyond the ſcales, and three ſhort, broadiſh, reddiſh, reflex ſtigmas[r]. According to Gærtner, one ſhort pyramidal ſtyle, with three ſtigmas. Acorn ovate-cylindrical, coriaceous, very ſmooth except at the baſe, where it is as if raſped, one-celled, valveleſs, received at bottom in a hemiſpherical cup, which is tubercled on the outſide. The germ is three-celled, with two embryos in each cell, faſtened to the baſe; but the fruit when ripe has only one cell, and commonly one ſeed, ſometimes two, very ſeldom three, correſponding exactly with the cavity of the nut, of a ferruginous colour[s].

Native of Europe; flowering in april. The fruit ripens in october.

Varieties.

Mr. Miller has made four ſpecies out of this:] 1. Q. Robur, the common Oak. 2. Q. fœmina, with the acorn on long peduncles. 3. Q. ſempervirens, or broad-leaved evergreen Oak. 4. Q. humilis, or dwarf Oak.

The firſt is the moſt common Oak of this country. The leaves have pretty long foot-ſtalks, and the acorns have none, but ſit cloſe to the branches.

The ſecond is not ſo common as the firſt, but in the wilds of Kent and Suſſex there are many large trees of this kind. The leaves are not ſo deeply ſinuated, nor are they ſo irregular, but the indentures are oppoſite; they have ſcarce any foot-ſtalks but ſit cloſe to the branches: but the acorns ſtand upon very long foot-ſtalks. The timber of this ſort is accounted better than that of the firſt, and the trees when growing have a better appearance. Theſe two have been generally regarded as ſeminal varieties, but having ſeen ſome young trees with acorns on them, which were raiſed from acorns of this ſecond ſort, and finding they retain their difference, I am inclined to believe they are different.

The third grows upon the Apennines and alſo in Suabia and Portugal. The leaves are broader and not ſo deeply ſinuated as thoſe of the common Oak; they are of a lighter green on their upper ſide, and pale on their under; they have very ſhort foot-ſtalks, and their points are obtuſe; the acorns have very long foot-ſtalks, which frequently ſuſtain three or four in a cluſter.

The fourth grows in the South of France and Italy; this is a low buſhy Oak, which riſes but ſix or ſeven feet high, ſending out many ſlender branches the whole length. Leaves oblong and obtuſely indented, about three inches long, and an inch and half broad, ſtanding upon ſlender footſtalks: acorns ſmall, growing in cluſters. The galls grow three or four together.

[Mr. Miller is miſtaken in affirming that the tree which bears ſeſſile acorns is the moſt common Oak of this country; and in referring us only to the wilds

[r] Pollich. [s] Gærtner.

Digitized by Google

of Kent and Suſſex for the other. This miſtake has been copied by Dr. Hunter in his edition of Evelyn's ſilva. His third ſort is only a variety of his ſecond; and it is not unuſual for ſome Oaks to retain their leaves till the ſpring. His fourth is probably a variety alſo of the ſecond, owing to ſoil and ſituation.

It is well obſerved by Monſ. Du Hamel, that Oaks in foreſts being propagated from the acorn, there are ſo many varieties, that it is difficult to find two reſembling each other in every reſpect. This is in great meaſure true, with reſpect to little variations in the ſhape and ſize both of the leaves and fruit, and ſome other ſubordinate circumſtances. There are alſo many varieties of Oak which dealers in timber and woodmen diſtinguiſh by their uſe, qualities and accidents, and to which they give different names; but theſe being merely local, and not founded on permanent characters, it is difficult to aſcertain them.

Du Hamel, following Tournefort, ſets down the ſpecies or varieties which are to be found in the pinax of Caſpar Bauhin, to the number of fourteen, and adds ſome others from Tournefort's corollary, &c. making twenty-three in the whole: but out of theſe, ſeven are natives of America or the Levant, and are probably diſtinct ſpecies. Boerhaave gives only five ſorts in his catalogue of the Leyden garden, but it is ſaid that he cultivated there no fewer than ſeventy ſpecies: if ſo, he muſt have had both many diſtinct ſorts of Oak, and many varieties of the common one.

Monſ. Fougeroux, in an ingenious eſſay on this ſubject, printed in the Memoirs of the French Academy for 1781, remarks, that Oaks commonly uſed for timber may be thus diſtinguiſhed: 1. *Quercus latifolia mas, quæ brevi pediculo eſt*, C. B. 2. *Q. cum longo pediculo*, C. B. 3. *Q. foliis molli lanugine pubeſcentibus*, C. B. called in French *Chêne noir* from the dark colour of the wood, and *Chêne blanc* from the white down on the under ſurface of the leaves. This he affirms to be the common Oak of England, the true *Robur* of the ancients, and the ſort that is taken by builders for Cheſtnut.

In this work I have followed the Kew catalogue in giving only three varieties of the common Oak. The third is of little ſignification, on account of its dwarf ſize: but the two others furniſh excellent timber. Our firſt variety ſeems to be Monſ. Fougeroux's ſecond ſort; and our ſecond variety to be his firſt ſort; the third of that gentleman being only an intermediate variety. The diſtinction of the firſt and ſecond is founded upon two obvious and ſeemingly permanent characters of the leaf and fruit.

The figures in old authors all ſeem to belong to our firſt variety, the acorns being evidently peduncled, and they do not notice the other. John Bauhin diſtinguiſhed the Oak with acorns on long peduncles, from that which bears them on ſhort ones; and Ray, who trod very much in his ſteps, thinks that theſe are ſpecifically different, becauſe the latter has the fruit not merely on ſhort peduncles, but with the cup ſeſſile or adhering cloſe to the branch[t]. The former with the acorns on long peduncles he regards as the common Oak of England, and when he writ his hiſtory, (1688) he ſuppoſed it to be the only one which is indigenous of this country. He was afterwards however informed by Bobart, that the Oak with acorns on ſhort foot-ſtalks is found in Bagley-wood and divers other places; and adds, that the leaves being of a darker green and leſs deeply ſinuate than the common Oak, it is known about Newbery by the name of Bay Oak[u]. It has been obſerved ſince in Norwood, Surrey. Mr. Ruggles diſcovered one only, a vigorous pollard, at leaſt two hundred years old, in his paddock at Cobham in Surrey, and could not find or hear of another in the neighbourhood[x]. It occurs however in many other places, though it is certainly much leſs common than the ſtalk-fruited Oak. Beſides the principal differences pointed out in the ſpecific characters, the ſeſſile-fruited or Bay Oak has the leaves of a deeper green, not ſo deeply indented as in the common one; they alſo appear later, and frequently remain on the tree all winter; the flowers alſo come out later, and of courſe the acorn is later. This is in cluſters from three or four to twelve. Mr. Lightfoot ſays, that it bears ſix or ſeven acorns in a cluſter, on very ſhort foot-ſtalks; that the leaves are leſs divided, of a firmer and more laurel-like (he ſhould have ſaid bay like) texture; that the tree itſelf is more humble; and the timber harder and higher-coloured. Du Roi affirms that the timber is reddiſh and brittle, whereas that of the ſtalk-fruited Oak is whitiſh and hard. If this ſhould turn out to be the caſe, it behoves planters of Oak for timber to attend to the diſtinctions given above, and to avoid gathering acorns for planting from ſuch trees as have the leaves or foot-ſtalks with ſeſſile fruits[y].

The wood of the Oak, when of a good ſort, is well known to be hard, tough, tolerably flexible and not eaſily ſplintering, ſtrong without being too heavy, and not eaſily admitting water; for theſe excellent qualities it is preferred before all other timber for building ſhips. It is alſo adapted to almoſt every purpoſe of the carpenter; and it would be difficult to enumerate all the uſes to which it may be applied. There is a kind of it, ſays Evelyn, ſo tough and compact, that our ſharpeſt tools will hardly enter it. Though ſome trees be harder, yet we find them more fragile, and not ſo well qualified to ſupport great weights, nor is there any timber more laſting, which way ſo ever uſed.

That which is twined and a little wreathed is beſt to ſupport burthens, for poſts, columns, ſummers, &c. for all which our Engliſh Oak is greatly preferable to the French: and it is found that the rough-grained body of a ſtubbed Oak is fitteſt for the caſe of a cyder-mill, and ſuch like engines, as beſt enduring the unquietneſs of a ponderous rolling ſtone. For ſhingles, pales, laths, cooper's ware, clap-board for wainſcot, much eſteemed in former times; for wheel-ſpokes, pins and pegs for tiling, Oak is excellent. The knottieſt is moſt proper for water-works, piles, &c. becauſe it will drive beſt, and laſt longeſt; the crooked yet firm for knee-timber in ſhipping, mill-wheels, &c. Coppice Oak makes the beſt hoops. The ſmaller trunchions and ſpray make billet, bavine and coals; poles, cudgels and walking ſtaffs. Of the roots were formerly made hafts for daggers, hangers and knives, handles for ſtaves, boxes, mathematical inſtruments, &c. &c.[z]

Oak ſaw-duſt is the principal indigenous vegetable uſed in dying fuſtian: all the varieties of drabs, and different ſhades of brown are made with Oak ſaw-duſt, variouſly managed and compounded.—Oak-apples are likewiſe uſed in dying, as a ſubſtitute for galls: the black got from them, by the addition of copperas, is more beautiful than that from galls, but not ſo durable. The galls upon the leaves, are occaſioned by a ſmall inſect called *Cynips querci folii*, which depoſits an egg in the ſubſtance of the leaf, by making a ſmall perforation on the under ſurface.—The bark is univerſally uſed to tan leather: an infuſion of it, with a ſmall quantity of copperas, is uſed by the common people to dye woollen of a purpliſh blue; the colour, though not very bright, is durable[a]. The highlanders in Scotland, dye their yarn with it of a brown colour: a herdſman there would think himſelf and his flock unfortunate, if he had not a ſtaff of it.—The ſaw-duſt, and even the leaves may be uſed for tanning; but they are much inferior to the bark for that purpoſe. The leaves are very ſubject to be covered with a ſweet viſcid juice, called honey-dew, which bees and other inſects are very fond of: the larvæ of many inſects feed upon them[b]. Where they are in quantity they may be uſed when dried for litter. By ſome they are preferred to dung for making hot-beds for melons; and may probably be uſed inſtead of the bark in tanning.

Suppoſing

Digitized by Google

Suppoſing Oak-bark to be ſold at five guineas a ton: in its marketable ſtate, it is by no means ſufficiently dry for preſervation; the tanners therefore are obliged to dry it more perfectly: they likewiſe get it cleaned from much extraneous matter at a conſiderable trouble and expenſe. The loſs of weight from theſe operations cannot be eſtimated at leſs than 20s. the ton. The ton of bark therefore ſtands the tanner in 6l. 5s.; for the ſake of eaſier calculation ſay 6l. The Rev. Mr. Swayne, of Pucklechurch, near Briſtol, had Oak-leaves collected for making hot-beds, at 3d. and 4d. the ſack of four buſhels; which, according to experiments made by him, are equal to thirty-two pounds of bark; which, at 6l. the ton, come to 1s. 8½d. and a fraction. It follows then that the tanner might obtain as much aſtringent matter in leaves for 4d. as coſts him in bark five times that ſum: whether it would equally anſwer his purpoſe, remains to be proved. There would be much trouble and ſome expenſe in drying the leaves, and they would occupy much room. Perhaps for theſe reaſons, the moſt œconomical plan would be, to obtain a concentrated extract from them, on or near the place where they ſhould be collected, which might be conveyed and ſtored in caſks. This likewiſe remains as the ſubject of experiment; but before leaves can be legally uſed by the tanner, the act of parliament confining him to the uſe of Aſh and Oak bark muſt be repealed. This reſtriction was probably laid; not ſolely from the belief that thoſe ſubſtances were the moſt proper for tanning leather, but likewiſe to encourage the planting and nurturing of thoſe valuable timber trees. Be this as it may, at preſent it rather operates to their deſtruction, than preſervation or increaſe; ſince the high price which Oak-bark now bears, proves an irreſiſtible temptation with needy proprietors to cut down their Oaks before they arrive at a proper age for timber. Should Oak leaves ever be in much requeſt for tanning, this doubtleſs would prove an antidote to the rage of felling, and an effectual preſervative of timber; ſince no one ſurely would ever think of felling his Oaks prematurely, whilſt they yielded him an annual profit by ſtanding *.

Acorns were of conſiderable importance formerly, when a great proportion of this iſland was foreſt, for feeding ſwine. About the end of the ſeventh century King Ina, among the few laws which he gave to regulate the ſimple œconomy of our Saxon anceſtors, gave particular directions relating to fatting ſwine in woods, ſince his time called *pawnage* or *pannage*.

In a ſucceeding century, Elfhelmus reſerves the pannage of two hundred hogs for his lady, in part of her dowry.

Maſt is particularly mentioned about the middle of the eleventh century in a donation of Edward the Confeſſor.

It appears from Domeſday-Book, that in William the Conqueror's time, Oaks were ſtill of no farther conſequence than from the food they afforded to ſwine; for the value of the woods, in ſeveral counties, is aſcertained by the number of hogs they would fatten. The ſurvey was taken ſo accurately, that in ſome places woods are mentioned of one hog.

Swine fed in the woods furniſhed ſo conſiderable a part of the food of former ages, that a ſcarcity of maſt was one of the cauſes of the frequent famines that then happened. The author of *Chronicon Saxonicum*, after deſcribing the extraordinary famine and mortality of the year 1116, records particularly the failure of maſt in that year.

Our Norman line of Kings, in their rage for extending foreſts for the chace, took away the right of pawnage from thoſe on whoſe lands they had encroached: this was one of the grievances that King John was compelled to redreſs in the *Charta de Foreſt*.

In Strabo's time, Rome was chiefly ſupplied with hogs, which were fatted on maſt in the woods of Gaul. That author alſo ſays, that in the mountainous parts of Spain, the inhabitants ground their acorns into meal. Pliny, who deſcribes very minutely the different effects of the various ſorts of acorns in the fattening of ſwine, informs us, that in his time, acorns were brought to table in Spain, for the deſert. It is probable that they ſtill continue to be eaten by the common people of that country, for they are produced after the repaſt of the goat-herds of Cervantes, and Tereſa ſends the Ducheſs a preſent of the choiceſt ſhe could collect [c]. But we muſt not eſtimate the taſte of the peaſants in the ſouthern countries of Europe, by the quality of our acorns: for the fruit of our common Oak is probably leſs bitter in a warmer climate: and the acorns generally eaten there are from another ſpecies.

The aſtringent effects of the Oak were well known to the ancients, by whom different parts of the tree were uſed; but it is the bark which is now directed for medicinal uſe by our pharmacopœias.

Oak bark manifeſts to the taſte a ſtrong aſtringency, accompanied with a moderate bitterneſs, qualities which are extracted both by water and ſpirit. Like other aſtringents it has been recommended in agues, and for reſtraining hæmorrhages, alvine fluxes, and other immoderate evacuations. A decoction of it has likewiſe been advantageouſly employed as a gargle, and as a fomentation or lotion in procidentia recti et uteri. Dr. Cullen frequently employed the decoction with ſucceſs in ſlight tumefactions of the mucous membrane of the fauces, in prolapſus uvulæ, and cynanche tonſillaris, to which ſome perſons are liable upon the leaſt expoſure to cold: in many caſes this decoction, applied early, has appeared uſeful in preventing theſe diſorders. Dr. Cullen almoſt conſtantly added a portion of alum to theſe decoctions; but he did not find a ſolution of alum alone ſo effectual.

Some have ſuppoſed that this bark is not leſs efficacious than that of the Cinchona, eſpecially in the form of extract; but this opinion now obtains little credit; though there is no doubt that Oak bark will cure intermittents, both alone and joined with chamomile flowers.

Galls appear to be the moſt powerful of the vegetable aſtringents, ſtriking a deep black when mixed with a ſolution of green vitriol, and therefore preferred to every other ſubſtance for the purpoſe of making ink. As a medicine they are to be conſidered as applicable to the ſame purpoſes as Oak-bark, and by poſſeſſing a greater degree of aſtringent and ſtyptic power, ſeem to have an advantage over it, and to be better ſuited for external uſe. Reduced to fine powder, and made into an ointment, they have been found of great ſervice in hæmorrhoidal affections. Their efficacy in intermittent fevers was tried by Monſ. Poupart, by order of the Academy of Sciences, and from his report it appears, that the Galls ſucceeded in many caſes; but that they failed in many others, which were afterwards cured by the Peruvian Bark.

Two ſorts of Galls are diſtinguiſhed in the ſhops; one ſaid to be brought from Aleppo, the other from the ſouthern parts of Europe. The former are generally of a blueiſh colour, or of a greyiſh, or black, verging to blueneſs, unequal and warty on the ſurface, hard to break, and of a cloſe compact texture: the others are of a light browniſh or whitiſh colour, ſmooth, round, eaſily broken, leſs compact, and of a much larger ſize. The two ſorts differ only in ſtrength, two of the blue Galls being ſuppoſed equivalent in this reſpect to three of the others [d].

The Oak is remarkable for its ſloweſs of growth, longevity and bulk.

It has been remarked that the trunk has attained to the ſize of twenty inches, and ſometimes not more than fourteen inches in diameter, in four-ſcore years. I have juſt meaſured an Oak in my poſſeſſion, which is nearly of that age, and is in circumference five feet three inches, at five feet above the ground. But ſize will depend much upon ſoil and ſituation.

The age of an Oak is commonly eſtimated at three

* Tranſact. Arts, vol. 10, for 1792. p. 153—163.

[d] Woodville.

hundred

Digitized by Google

hundred years. Tradition carries ſome trees which have eſcaped the axe to an antiquity much more remote. Mr. Gilpin ſpeaks of a few venerable Oaks in the New Foreſt, that chronicle on their furrowed trunks ages before the conqueſt[e]. Mr. Evelyn mentions three fine Oaks in Dennington-park, as an inſtance of the bulk and ſtature to which this tree may arrive within leſs than three hundred years. Sir Edward Harley relates, that he was aſſured by an inquiſition taken about three hundred years ſince, that a park of his, and ſome adjacent woods, had not then a tree capable to bear acorns; yet that very park he had ſeen full of great Oaks, and moſt of them in the extremeſt wane of decay. Mr. Evelyn informs us, that from three to four hundred rings were diſtinguiſhed in ſome trees cut down in the New Foreſt.

The ſame great planter ſets down the age for felling the Oak at between fifty and ſixty years growth[f]. This is when the trees in general are in the greateſt perfection. The Biſhop of Landaff mentions it as a general opinion, that it is more profitable to ſell Oak timber at this age, than to let it ſtand to eighty or one hundred; according to the price now paid for it, he believes the opinion to be founded in truth, and it is confirmed by Mr. Marſham's tables of the growth of trees in the Philoſophical Tranſactions for 1759. The learned Prelate lays down a general rule, that conſidering profit only, every tree of every kind ought to be cut down and ſold, when the annual increaſe in value, by its growth, is leſs than the annual intereſt of the money it would ſell for. From obſervation on Mr. Marſham's tables the Biſhop fixes upon 30s. as the value of trees which ſhould be cut down for mere profit, the proprietor being a loſer, if they are cut ſooner or later. Unleſs therefore the Navy-board would give 8l. or 9l. a load for timber trees containing one hundred cubic feet or upwards, inſtead of 4l. or 5l. it is every man's intereſt to cut down his trees before they attain that ſize, and conſequently little dependance can be placed on private property for a ſupply of naval timber[g].

Of the bulk, ſtature and extent of the Oak we have abundance of recorded inſtances. In Workſop-park there was a tree ſpreading almoſt three thouſand yards ſquare, ſo that under the ſhade of it near a thouſand horſe might commodiouſly ſtand at once. Dr. Plot mentions an Oak at Narbury, of fifteen yards in girth, which being felled, two men at either ſide on horſeback could not ſee one another.

An Oak at Reedham in Norfolk in Sir Richard Berney's park, was valued at 40l. and 12l. the lopping wood.

Of the three Oaks, ſaid to be planted by Chaucer, in Dennington-park near Newbury, one called the King's Oak was fifty feet in height before any bough or knot appeared, and cut five feet ſquare at the but-end, all clear timber. The ſecond, called the Queen's, held forty feet excellent timber, ſtraight as an arrow in growth and grain, cutting four feet at the ſtub, and near a yard at the top: beſides a fork of almoſt ten feet clear timber above the ſhaft. The third, called Chaucer's Oak, though it were not of theſe dimenſions, yet was it a very goodly tree. The diameter of the Oak that afforded the beams of the Royal Sovereign was four feet nine inches, and yielded four ſquare beams of forty-four feet in length each. It grew near Framlingham in Suffolk.—Dr. Plot mentions an Oak between Nuneham Courtney and Clifton, ſpreading eighty-one feet, ſhading in circumference five hundred and ſixty yards of ground, under which two thouſand four hundred and twenty men may commodiouſly ſtand in ſhelter. And a bigger than this near the gate of the water-walk at Magdalen College, Oxford, the branches of which ſhoot ſixteen yards from the ſtem; likewiſe another at Ricot, extending its arms fifty-four feet, under which three hundred and four horſes or four thouſand three hundred and ſeventy-four men may ſufficiently ſtand[h].

Mr. Evelyn has given an account of many other large Oaks in Yorkſhire, Nottinghamſhire, &c. from Mr. Halton, auditor to the Duke of Norfolk.

In the St. James's Chronicle, n. 5038. it is ſaid that an Oak was felled a few days before at Morley in Cheſhire, which produced upwards of a thouſand meaſurable feet of timber. Its girt was fourteen yards, and one branch contained two hundred feet. Its exiſtence can be traced back for eight hundred years, and it was ſuppoſed to be the largeſt tree in England; as a proof of it; the trunk has been uſed ſome years for houſing cattle; and it is ſaid Edward the Black Prince once dined under it.

In Dodſley's Annual Regiſter for 1758, p. 116. mention is made of an Oak in Langley-wood, near Downton, Wilts, the property of the Biſhop of Saliſbury, ſuppoſed to be of near one thouſand years growth. It was ſix feet two inches in diameter, contained about ten tons of timber, and was ſold for 40l.

An Oak on Sir John Barnard's eſtate in Huntingdonſhire, contained ſeven hundred and fifty feet of timber, which at 2s. a foot was worth 75l.

The contents of an Oak felled at Withy-park, near Wenlock in Shropſhire in 1697 were as follows:

The ſpread from out bough to out bough was forty-eight yards. The trunk was nine feet in diameter, beſides the bark. It contained twenty-four cords of yard wood, worth 9l. 10s. and eleven cords and a half of four feet wood worth 12s. per cord; two hundred and fifty-two park pales, ſix feet long: ſix tons and a half of timber in the boughs: one load of cooper's ware: twenty-eight tons of timber in the body. All this beſides faggots. The ſtem was ſo wide, that two men might threſh on it without ſtriking each other. Several boughs dropped off in Mr. Weld's father's and grandfather's times.

In Holt-foreſt in Hampſhire, near Bentley, not far from Farnham in Surrey, an Oak in 1759 girted thirty-four feet, at ſeven feet from the ground. In 1778 this tree was increaſed only half an inch.

In Workſop-park were three Oaks: the firſt of which girted thirty feet: the ſecond ſpread one hundred and eighty feet or 2827 ſquare yards, which is above half an acre: the third had forty feet of timber in it, two feet ſquare at the top end, and contained ſix tons and a quarter of timber.

Shire Oak, near Workſop-park, is ſo named becauſe it drops into three ſhires, viz. York, Nottingham and Derby: the ſpread ninety feet, or 707 ſquare yards.

Lady Oak was five feet ſquare for forty feet in length; it had twenty tons of timber, and the boughs yielded twenty-five cords of fuel wood.

An Oak at Cowthorpe, near Wetherby in Yorkſhire, within three feet of the ſurface meaſures ſixteen yards in girt, and cloſe to the ground twenty-ſix yards: its height in 1776, was about eighty-five feet; and its principal bough extended ſixteen yards. It is now thin of leaves, and in a ſtate of decay. It is figured in the ſecond volume of Dr. Hunter's edition of Evelyn's Silva, at p. 197. Mr. Marſham ſays, that in 1768, at four feet it girted forty-ſix feet ſix inches: at five feet thirty-ſix feet ſix inches: and at ſix feet thirty-two feet one inch.

Mr. Marſhall gives the following account of the Boddington Oak, growing in the old orchard ground belonging to Boddington Manor farm, near the turnpike road between Cheltenham and Tewkſbury in the vale of Gloceſter. The ſtem is remarkably collected and ſnug at the root, the ſides of its trunk being more upright than thoſe of large trees in general; nevertheleſs its circumference at the ground, as near to it as one can walk, is twenty paces: meaſuring with a rule, it is ſomewhat more than eighteen yards. At three feet high it meaſures forty-two feet, and at its ſmalleſt dimenſions, namely from five to ſix feet high, it is thirty-ſix feet. At about ſix feet it begins to ſwell out larger; forming an enormous head, which heretofore has been furniſhed with huge, and in all probability extenſive arms. But age and winds have robbed it of a principal part of its grandeur; and the greateſt extent of arm in 1783 was eight yards from the ſtem. From the ground to the top of the trunk is

[e] Foreſt ſcenery, 2. 63. [f] Sylva, b. 3. ch. 3.

[h] Evelyn's Silv. 3. 3.

Digitized by Google

is about twelve feet, and the greateſt height of the branches by eſtimation forty-five feet. The ſtem is quite hollow, being, near the ground, a perfect ſhell, forming a room, which at the floor meaſures one way more than ſixteen feet in diameter; it is a natural dome at top, and no light is admitted except at the door, and an aperture in the ſide. That year it had a fine crop of acorns on it. The leaves, as generally on old trees, are very ſmall; not larger, for the moſt part, than thoſe of the Hawthorn.

Theſe very old Oaks have generally ſhort ſtems, at ſix, eight, ten, or twelve feet high throwing out large horizontal arms. The Oak however will acquire a great length of ſtem, but then it rarely ſwells to any conſiderable girt. Mr. Marſham indeed mentions one in the Earl of Powis's park near Ludlow, which in 1757 meaſured, at five feet high ſixteen feet three inches, and which ran quite ſtraight and clear of arms near or full ſixty feet.

Mr. Lightfoot mentions an Oak belonging to Lord Powis, in Broomfield-wood, near Ludlow in Shropſhire, in the year 1764, the trunk of which meaſured ſixty-eight feet in girt, twenty-three in length, and which, reckoning ninety feet for the larger branches, contained in the whole one thouſand four hundred and fifty-five feet of timber, round meaſure, or twenty-nine loads and five feet, at fifty feet to a load.

There are ſeveral fine Oaks in Welbeck-park. Sixty pounds was offered for one of them. That which is called the Duke's walking-ſtick is one hundred and eleven feet ſix inches in height; ſeventy feet ſix inches up to the branches; the circumference at bottom twenty-one feet, at one yard high fourteen feet, at two yards high twelve feet; ſolid contents four hundred and forty feet; weight eleven tons.—Two Oaks called the Porters: the height of one ninety-eight feet ſix inches; the circumference at bottom thirty-eight feet, at one yard high twenty-ſeven feet, at two yards twenty-three feet; ſolid contents eight hundred and forty feet: the other eighty-eight feet high, the circumference at bottom thirty-four feet, at one yard twenty-three feet, at two yards twenty feet; the ſolid contents ſeven hundred and forty-four feet.

The Greendale Oak, thought to be above ſeven hundred years old: the circumference thirty-five feet three inches[1]. Dr. Hunter gives the dimenſions thus: Circumference at one foot from the ground thirty-three feet one inch, at two feet twenty-eight feet five inches, at ſix feet twenty-five feet ſeven inches: ſpread eighty-one feet: the whole height eighty-eight feet. There are prints of this tree in its ſtate of ruin in the ſecond volume of Dr. Hunter's edition of Evelyn's Silva.

In this park is a fine grove of large Oaks meaſuring from twelve to twenty-two feet in circumference.

On the hills at the eaſt end of the park are plantations, chiefly of Oak and Cheſtnut, with ſome Beech, Larch, Weymouth Pine, and Firs, near four hundred acres, all planted by the preſent Duke of Portland.

There are ſeveral fine Oaks in Welbeck-park in full vigour, above five hundred years old.

On Sherwood-foreſt, five miles from Welbeck is a beautiful wood of above ten thouſand old Oaks, with Birches intermixed, whence it is called Birchland; the whole about one thouſand eight hundred acres. On the north ſide of the great riding is a curious ancient Oak, meaſuring near the ground thirty-four feet four inches, at one yard twenty-ſeven feet four inches, at two yards thirty-one feet nine inches. It cannot be leſs than one thouſand years old.—An Oak cut down in Birchland, had the letters J. R. more than a foot within the tree, and about a foot from the centre; ſo that it muſt have been near ſix feet in circumference when the letters were cut out. A tree of that ſize is judged to be about one hundred and twenty years growth. If we ſuppoſe the letters to be cut about the middle of James the Firſt's reign, it is one hundred and ſeventy-two years to the year 1786, when the tree was cut down, which added to one hundred and twenty, makes the tree two hundred and ninety-two years old. It was perfectly ſound, and had not arrived to its higheſt perfection. It was about twelve feet in circumference [k].

Fiſher's Oak, about ſeventeen miles from London, or half way to Tunbridge, of a monſtrous bulk; the trunk only remaining of above four fathoms in compaſs. When King James the Firſt made a progreſs that way, a ſchool-maſter of the neighbourhood and all his ſcholars dreſſed in oaken garlands came out of this tree in great numbers, and entertained the King with an oration. They have a tradition at Tunbridge, that thirteen men on horſeback were once ſheltered in this Oak.

In the hall at Goodrich-caſtle in Herefordſhire was a beam of Oak without knot, ſixty-ſix feet long, and near two feet ſquare the whole length [l].

At Selborne, in the county of Southampton, about the year 1768, twenty trees were felled in a little wood, tall and taper like firs, with only a little bruſh at the top, and without any large limbs, from fifty to ſixty feet in the trunk, and twelve inches diameter at the ſmall end: they ſold for 20l. a tree.

The lawn of the Duke of Bolton's Lodge at Bulley is adorned with ſome very grand Oaks, which from the dignity of their form, and venerable appearance, as well as the number of the moſt reſpectable of them have obtained the name of the twelve Apoſtles [m].

An Oak was felled in april 1791, in the park of Sir John Ruſhout, Bart. at Northwick, near Blockley in Worceſterſhire, judged to be about three hundred years old, perfectly ſound and fine timber.

In Whittlewood foreſt Mr. Arthur Young meaſured Wake's Oak, which is the ruins of a noble tree, twenty feet three inches in circumference at five feet from the ground; and twenty-five feet eight inches at two feet. Raven's Oak, ſixteen feet inches at five feet. The Lawnhead Oak, fixteen feet ſix inches [n].

In Hainault foreſt, Eſſex, ſtands a remarkable tree, well known by the name of Fairlop Oak. The ſtem, which is rough and fluted, meaſures, at three feet from the ground, about thirty-ſix feet in girt. The boughs extend about three hundred feet in circumference. Under their ſhade, on the firſt friday in july, is held a fair, founded by Mr. Daniel Day, who uſed annually to dine there on that day with a ſelect party of friends. The tree is now fenced round with a cloſe paling about five feet high, and Mr. Forſyth's compoſition has been applied to its decayed branches, to preſerve it from future injury. The Hainault Foreſters, one of the ſocieties formed for the purpoſe of enjoying the amuſement of archery, held their meetings near this Oak [o].

Mr. Gilpin mentions Arthur's table, in the town-hall of Winchefter, cut out of a tree of immenſe girt. The Cheltenham Oak, which as near its roots as you can walk, exceeds twenty paces round. The Swilter Oak in Needwood foreſt, which he believes was equal to any of them [p]. He is very particular on the Oak which ſtood by the gate of the water-walk at Magdalen college in Oxford, mentioned above. He amuſes himſelf with the idea that it was a ſaplin

when Alfred the Great founded the Univerſity, a period including *only* a ſpace of nine hundred years, which is no great age for an Oak! About five hundred years after the time of Alfred, William of Wainfleet, Dr. Stukeley tells us, ordered his college to be founded near the *great Oak*; and an Oak could not be leſs than five hundred years of age, to merit that title, together with the honour of fixing the ſite of a college. It was much injured in Charles the Second's time, when the preſent walks were laid out: the roots were then diſturbed, from that period it declined faſt, and became reduced by degrees to little more than a mere trunk. It once could have ſheltered with eaſe three thouſand men, though in its decayed ſtate, it could for many years do little more than ſhelter ſome luckleſs individual from the driving ſhower. In the ſummer of 1788, this magnificent ruin fell to the ground. Its grand tap-root was decayed, and it had hold of the earth only by two or three roots, of which no one was more than two inches in diameter. From a part of its ruins a chair was made for the preſident of the college, which will long continue its memory [q].

From a note in my poſſeſſion, probably in ſome periodical publication of the time, it appears that this Oak fell ſuddenly at four o'clock on monday morning, june 29th, 1789.

The girt was 21 feet, 9 inches.
Height 71 feet, 8 inches.
Cubic contents 754 feet.

The trunk for more than nine feet from the ground, was reduced to a perfect ſhell, but upwards the tree ſeemed in the full vigour of vegetation.

Not far from Blandford in Dorſetſhire ſtood a tree known by the name of Damory's Oak. At the ground its circumference was ſixty-eight feet; and ſeventeen feet above the ground its diameter was four yards. As this vaſt trunk decayed, it formed a cavity fifteen feet wide and ſeventeen high, capable of holding twenty men. During the civil wars and after the reſtoration, this cave was inhabited by an old man, who ſold ale in it. By the ſtorm of 1703, it loſt many of its nobleſt limbs. But forty-five years after that, ſome of its branches were ſeventy-five feet high, and extended ſeventy-two feet. In the year 1755, when it was fit for nothing but fire-wood, it was ſold for 14l.[r]

In Torwood, in the county of Sterling, ſtand the ruins of an Oak, ſuppoſed to be the largeſt tree that ever grew in Scotland. It is now hollow, but from what remains it is evident that the diameter of the trunk could not have been leſs than eleven or twelve feet. It is probably a tree of great antiquity; the veſtiges of a circle round it reſemble thoſe works which are commonly attributed to the Druids. When William Wallace rouſed the Scotch nation to oppoſe the tyranny of Edward, he often aſſembled his army at Torwood, and then this Oak is ſaid to have been his head quarters; hence it has ever ſince been known by the name of *Wallace tree* [s].

Herne's Oak, celebrated by Shakſpeare, is ſaid ſtill to exiſt in the little park at Windſor, in Queen Elizabeth's walk, all the trees in which are Elms, except this. It is a large tree, meaſuring about twenty-four feet in circumference, and ſeems yet too vigorous to have been a proper tree for Herne the hunter to have danced round, more than two centuries ſince.

An Oak in the grounds of Sir Gerard Vanneck, at Heveningham in Suffolk, carries us likewiſe into the times of Elizabeth. It is now falling faſt into the decline of years. Its trunk, which meaſures thirty-five feet in circumference, ſtill maintains its grandeur, but in appearance only, for it is a mere ſhell. In Queen Elizabeth's time it was hollow. That princeſs, who from her earlieſt age loved maſculine amuſements, uſed often, it is ſaid, in her youth, to take her ſtand in this tree, and ſhoot the deer as they paſſed. From that time it has been known by the name of Queen Elizabeth's Oak [t].

[q] Idem, p. 135.
[r] Idem, from Hutchins's Dorſetſhire, where is a print of it.
[s] Idem, from Nimma's Sterl. p. 145. [t] Idem, p. 145, 147.

The Oak tree in the New Foreſt in Hampſhire, againſt which the arrow of Sir Walter Tyrrel glanced, and killed King William Rufus, about ſixty years ago became ſo decayed and mutilated, that the ſpot would probably have been forgotten, had not John Lord Delaware, who lived in one of the neighbouring lodges, erected a triangular ſtone, with an inſcription on each face, before the ſtump was eradicated [u].

The Cadenham Oak, in the New Foreſt, near the village of Cadenham, about three miles from Lyndhurſt, buds every year in the depth of winter, and like the Glaſtonbury Thorn is believed by the country people to produce its buds only on old chriſtmas-day: theſe premature buds, after unfolding themſelves, make no farther progreſs, but ſhrink and die; the tree vegetating again at the uſual ſeaſon, and being in full leaf in the middle of ſummer, without any difference, form or foliage, from other Oaks [x].

The Oak which was planted at Penſhurſt on Sir Philip Sidney's birth-day ſtill remains, and is twenty-two feet round [y].

Mr. Collinſon makes mention of an Oak at Curry-Rivel in Somerſetſhire, which bears acorns more than thrice the uſual dimenſions; and by ſome experiments made by an eminent naturaliſt, it appears, that the plants which they produce grow twice as faſt as thoſe raiſed from common acorns [z].

Many places in England are named from this favourite tree: as Barkſhire, from a bare Oak, at which the people of that ſhire uſed to aſſemble; Oakingham, Oakhampton, Oakington, Aukland, Oxenham, Baldock, Hatfield Broad-Oak, Acca in Somerſetſhire, in Doomſday book, &c. &c.

The Oak at Boſcobell, which ſheltered King Charles the Second after the battle of Worceſter, and thence was called the Royal Oak, was famous in the laſt century. Several trees were raiſed from the acorns. One of theſe was in the botanic garden at Chelſea. Another was removed, when Marlborough houſe was built in St. James's-park.

The particular and moſt valued qualities of the Oak, ſays Mr. Gilpin, are *hardneſs* and *toughneſs*. Box and Ebony are harder, Yew and Aſh are tougher than Oak; but no timber is poſſeſſed of both theſe qualities together in ſo great a degree as Britiſh Oak. Almoſt all arts and manufactures are indebted to it; but in ſhip-building and bearing burdens, its elaſticity and ſtrength are applied to moſt advantage. It is not the erect, ſtately tree that is always the moſt uſeful in ſhip-building; but more often the crooked one, forming ſhort turns and elbows, commonly called *knee-timber*. Nor is it the ſtraight, tall ſtem, with the fibres running in parallel lines, that is the moſt uſeful in bearing burdens, but the "unwedgeable and gnarled Oak," as Shakſpeare calls it.

Virgil has brought together, in few words, the moſt obvious qualities of this noble tree, in one point of view:

"Eſculus imprimis, quæ quantum vertice ad auras
"Ætherias, tantum radice in Tartara tendit.
"Ergo non hiemes illam, non flabra, neque imbres
"Convellunt: immota manet, multoſque per annos
"Multa virûm volvens durando ſecula vincit.
"Tum fortes late ramos, ac brachia tendens
"Huc illuc, media ipſa ingentem ſuſtinet umbram [a]."

The firſt characteriſtic of the Oak which Virgil mentions, is its firmneſs, or the ſtrength with which it takes hold of the ground; driving its tap-root to a depth equal to the height of the tree. No tree therefore reſiſts the blaſt ſo ſteadily; and we ſeldom ſee it take a twiſted form from the winds. A ſecond characteriſtic is the ſtoutneſs of its limbs. We know not any tree, except perhaps the Cedar of Lebanon, ſo remarkable in this reſpect. The limbs of moſt trees ſpring from the trunk. In the Oak they may be rather ſaid to divide from it. You hardly know which is ſtem and which is branch; and towards the top, the ſtem is entirely loſt in the branches. This gives particular propriety to Virgil's epithet *fortes* in

[u] Idem, p. 160. [x] Idem, 165. [y] Gough's Camden.
[z] Somerſetſhire, 1. 24. [a] Georg. 2. 290.

characterizing

Digitized by Google

characterizing the boughs of the Oak, and hence its ſinewy elbows are of ſuch peculiar uſe in ſhip-building. The next characteriſtic of the Oak noticed by the poet is the twiſting of its arms: *brachia tendit huc illuc.* Examine almoſt any other tree, and you may obſerve in what direct and ſtraight lines the branches ſhoot from the ſtem: whereas the limbs of an Oak are continually making various contortions, and ſport and play in every poſſible direction. Another peculiarity which Virgil notices in the Oak, is its expanſive ſpread. This is a juſt characteriſtic of it; for its boughs, however twiſted, continually take a horizontal direction, and overſhadow a large ſpace of ground. Indeed, where it is fond of its ſituation, and has room to ſpread, it extends more than any other tree, and like a monarch takes poſſeſſion of the ſoil. The laſt Virgilian characteriſtic of the Oak is its *longevity*. In age it exceeds any other tree, except perhaps the Yew.

The Oak is confeſſedly the moſt pictureſque tree in itſelf, and the moſt accommodating in compoſition. It refuſes no ſubject, either in natural or in artificial landſcape. It is ſuited to the grandeſt, and may with propriety be introduced into the moſt paſtoral. It adds new dignity to the ruined tower and gothic arch; it throws its arms with propriety over the purling brook or the mantling pool; and may be happily introduced even in the loweſt ſcene:

> "Hard by a cottage chimney ſmokes
> "From between two aged oaks[a]."]

25. This is one of the faireſt ſpecies of Oak. The trunk riſes as high as that of the common Oak; the branches extend very wide on every ſide, and are covered with a grayiſh bark, intermixed with brown ſpots. Leaves about three inches long, and almoſt two inches broad, deeply cut with moſt of the teeth turning back and terminating in acute points; they are ſtiff, of a pale green on their upper ſide, and downy on their under. The acorns have very large ſcaly cups, which almoſt cover them; the ſcales are woody and pointed, ſtanding out a quarter of an inch; ſome of the cups are as large as middling Apples.

Native of the Levant, whence the acorns are annually brought to Europe for dyeing; they are called *Velani* and the tree *Velanida*, by the Greeks. [*Vallonia* at Venice. It is alſo found in Spain, Carniola, Piedmont, and Dalmatia. Mr. Miller cultivated it in 1731[c]. He ſays there were few in England about the year 1760, and that the greateſt part of theſe were raiſed in the Chelſea garden in 1748[d].]

26. The leaves of this are oblong and pointed, and are frequently lyrate; they are jagged and acute-pointed, a little hoary on their under ſide, and ſtand on ſlender foot-ſtalks. The acorns are ſmall, and have rough prickly cups.

[Native of the South of Europe. Cultivated in 1739, by Mr. Miller. There are ſeveral varieties of it[e]. The Lucombe or Devonſhire Oak is one. An account of it may be ſeen in the ſixty-ſecond volume of the Philoſophical Tranſactions.

Mr. Gilpin ſays it is nearly an ever-green, named from the perſon who raiſed it, produced from an acorn of the common Turkey Oak, from which all theſe have been grafted. It is ſaid the growth is rapid; but from few trees, and thoſe but young, no judgment can well be formed[f].]

PROPAGATION AND CULTURE.

All the ſorts of Oak are propagated by ſowing their acorns, and the ſooner they are put into the ground after they are ripe, the better they will ſucceed; for they are very apt to ſprout where they are ſpread thin, and if they are laid in heaps, they ferment and rot in a little time; the beſt ſeaſon therefore for ſowing them is the beginning of november, by which time they will be fallen from the trees.

[This early ſowing ſeems to be the moſt natural, but the deſtruction made by the Field Mouſe has induced many to prefer ſpring-ſowing.

Seedſmen, when they preſerve acorns for this purpoſe, lay them thin upon a boarded floor, where, if full ripe, they will retain their vegetative power during the winter[g].]

I ſhall firſt give directions for raiſing the ſeveral ſorts of Oak in a nurſery, when they are intended to be planted out for ornament, and the timber is not regarded. Theſe acorns may be ſown in beds four feet wide, with paths of two feet broad between them: in theſe beds there may be four rows ſown, at about nine inches diſtance from each other. [Others allow only four inches between the rows.] Draw ſtraight drills with a hoe, into which drop the acorns two or three inches apart, covering them carefully with the earth, two inches thick.

In the ſpring, when the plants begin to appear, clear them carefully from weeds, and if the ſeaſon prove dry, refreſh them now and then with a little water. Let them remain until the following autumn: at which time have a ſpot of ground, in ſize proportioned to the quantity of plants, well trenched and levelled; at the middle or end of october carefully take up the plants, ſo as not to injure their roots, and plant them out in rows three feet aſunder, and eighteen inches apart in the rows; never ſuffering the plants to abide long out of the ground, ſo as the roots may become dry.

[This work may be done in march, if there was not time for it in the autumn. Deep trenching or double digging being very expenſive, thoſe who plant on a large ſcale, may take a crop of Oats, Rape or Turneps off the land, the year before they plant, by which means the ſward may be effectually deſtroyed, and the land cleaned. After the crop is off, let the ground be trench-ploughed, and then harrowed with heavy harrows. About the end of october let it be again ploughed croſs-wiſe, and harrowed as before, previous to the planting of the ſets.

In planting theſe, having carefully taken them out of the ſeed-bed, ſhorten the tap-root, and take off part of the ſide ſhoots. Each line ſhould have a man and boy: the man ſtrikes his ſpade into the earth cloſe to the line; he gives another ſtroke at right angles with it: then the boy having a parcel of plants under his left arm, takes one with his right hand, and puts it into the crevice made by the ſpade at the ſecond ſtroke: after this, the man gently preſſes the mould to it with his foot. An active man and boy will thus plant fifteen hundred or two thouſand in a day; and whilſt they are planting, others ſhould be employed in taking up freſh ſets, ſorting them, and preparing the roots. There ſhould be a ſufficient number of hands, for the ground cannot be too ſoon planted when it is ready; neither can the plants be put in too ſoon, after they are taken up. The weakeſt plants may be left a year longer, to gain ſtrength[h].]

When the plants have taken root in the nurſery, they will require little more care than to keep them clear from weeds, and dig the ground between the rows every ſpring; in doing which, you ſhould cut off ſuch roots as extend very far from the trunk of the trees, which will render them better for tranſplanting again; you ſhould alſo prune off ſuch ſide-branches as extend themſelves very far, and would retard the upright ſhoot; but you ſhould by no means cut off all the ſmall lateral branches, ſome of which are abſolutely neceſſary to be left on, to detain the ſap for the augmentation of the trunk; for I have often obſerved, where trees have been thus cloſely pruned, that their heads have overgrown their bodies, ſo that they have bent downward and become crooked.

When theſe trees have remained in the nurſery three or four years, they will then be large enough to tranſplant to the places where they are to remain; for it is not proper to let them grow very large before they are planted out, becauſe theſe are very hazardous trees to remove when old, or after they have taken deep root.

Digitized by Google

The ſeaſon for this work is (as I ſaid before) in the autumn; at which time, if they are carefully taken up, there will be little danger of their ſucceeding. In tranſplanting theſe trees, by no means cut their heads, which is too much practiſed; all that ſhould be done, muſt be only to cut off any bruiſed or ill-placed branches, which ſhould be taken off cloſe to the place where they are produced; but there can be no greater injury done to theſe trees, than to ſhorten their ſhoots; for when the leading bud (which is abſolutely neceſſary to draw and attract the nouriſhment) is taken off, the branch often decays entirely, or at leaſt down to the next vigorous bud.

The trees thus raiſed and managed, will, (if planted in a proper ſoil) grow to a conſiderable magnitude, and are very proper for a wilderneſs in large gardens, or to plant in clumps in parks, &c. but if they are deſigned for timber, it is much the better method to ſow the acorns in the places where they are to remain; in order to which, provide yourſelf in autumn with a ſufficient quantity of acorns, which ſhould be always taken from ſtraight, upright, vigorous growing trees; theſe ſhould be gathered from under the trees as ſoon as may be after they are fallen; and, if poſſible, in a dry time, laid thin in ſome open room to dry; after which they may be put into dry ſand, and preſerved in a dry place until the beginning of november, when you ſhould prepare the ground for planting them.

The directions before given are deſigned only for ſmall plantations in a garden or park, which are only for pleaſure; but where theſe trees are cultivated with a view to profit, the acorns ſhould be ſown where the trees are deſigned to grow; for thoſe which are tranſplanted will never grow to the ſize of thoſe which ſtand where they are ſown, nor will they laſt near ſo long ſound. For in ſome places, where theſe trees have been tranſplanted with the greateſt care, and they have grown very faſt for ſeveral years after, yet they are now decaying, when thoſe which remain in the place where they came up from the acorns, are ſtill very thriving, and have not the leaſt ſign of decay. Therefore, whoever deſigns to cultivate theſe trees for timber, ſhould never think of tranſplanting them, but ſow the acorns on the ſame ground where they are to grow; for the timber of all thoſe trees which are tranſplanted, is not near ſo valuable as that of the trees from acorns. I ſhall therefore add ſome plain directions for ſowing acorns, and managing young trees during their minority, until they are out of danger, and require no farther care.

The firſt thing to be done is that of fencing the ground very well, to keep out cattle, hares and rabbets; for if theſe can get into the ground, they will ſoon deſtroy all the young trees. Indeed they will in a few years grow to be out of danger from hares and rabbets, but it will be many years before they will be paſt injury from cattle, therefore durable fences ſhould be put round the ground: if in the beginning a pale fence is made about the land, which may be cloſe at the bottom and open above, and within the pale a Quick-hedge planted, this will become a good fence by the time the pale decays, againſt all ſorts of cattle; and then the trees will have got above the reach of hares and rabbets, ſo that they cannot injure them, for the bark of the trees will be too hard for them to gnaw.

After the ground is well fenced, it ſhould be prepared, by ploughing it three or four times, and after each ploughing to harrow it well, to break the clods, and cleanſe the ground from Couch, and the roots of all bad weeds. Indeed if the ground is green ſward, it will be better to have one crop of Beans, Peas, or Turneps off the ground, before the acorns are ſown, provided theſe crops are well hoed to ſtir the ſurface and deſtroy the weeds; for if this is obſerved, the crop will mend and improve the land for ſowing; but in this caſe the ground ſhould be ploughed as ſoon as poſſible, when the crop is taken off, to prepare it for the acorns, which ſhould be ſown as ſoon as may be after the acorns are ripe; for although theſe may be preſerved in ſand for ſome time, yet they will be apt

to ſprout; and if ſo, the ſhoots are in danger of being broken and ſpoiled; therefore I ſhould adviſe ſowing early, which is certainly the beſt method:

In making choice of the acorns, all thoſe ſhould be preferred, which are taken from the largeſt and moſt thriving trees; and thoſe of pollard-trees ſhould always be rejected, though the latter are generally the moſt productive of acorns, but thoſe of the large trees commonly produce the ſtrongeſt and moſt thriving plants.

The ſeaſon for ſowing the acorns being come, and the ground having been ploughed and levelled ſmooth, the next work is to ſow the acorns, which muſt be done by drawing drills acroſs the ground, at about four feet aſunder, and two inches deep, into which the acorns ſhould be ſcattered at two inches diſtance. Theſe drills may be drawn either with a drill plough, or by hand with a hoe; but the former is the moſt expeditious method, therefore in large plantations ſhould be preferred. In drawing the drills, if the land has any ſlope to one ſide, theſe ſhould be made the ſame way as the ground ſlopes, that there may be no ſtoppage of the wet by the rows of plants croſſing the hanging of the land. This ſhould be particularly obſerved in all wet ground, or where the wet is ſubject to lie in winter, but in dry land it is not of much conſequence. When the acorns are ſown, the drills ſhould be carefully filled in, ſo as to cover the acorns ſecurely; for if any of them are expoſed, they will entice the birds and mice; and if either of theſe once attack them, they will make great havock with them.

The reaſon of my directing the drills to be made at this diſtance, is for the more convenient ſtirring the ground between the rows, to keep the young plants clear from weeds; for if this is not carefully done, it cannot be expected that the young plants ſhould make much progreſs; and yet this is generally neglected by many who pretend to be great planters, who are often at a large expenſe to plant, but ſeldom regard them after; ſo that the young plants have the difficulty to encounter the weeds, which are frequently four or five times the height of the plants, and not only ſhade and draw them, but alſo exhauſt all the goodneſs of the ground, and conſequently ſtarve the plants. Therefore, whoever hopes to have ſucceſs in their plantations, ſhould determine to be at the expenſe of keeping them clean for eight or ten years after ſowing, by which time the plants will have obtained ſtrength enough to keep down the weeds; the neglecting of this has occaſioned ſo many plantations to miſcarry, as are frequently to be met with in divers parts of England.

About the middle of april the young plants will appear above ground; but before this, if the ground ſhould produce many young weeds, it will be good huſbandry to ſcuffle the ſurface over with Dutch hoes, in a dry time, either the latter end of march or the beginning of april, to deſtroy the weeds, whereby the ground will be kept clean until all the plants are come up ſo as to be plainly diſcerned; by which time it may be proper to hoe the ground over again, for by doing it early, while the weeds are ſmall, a man will perform more of this work in one day than he can in three or four when the weeds are grown large; beſides, there will be great hazard of cutting off or injuring the young plants when they are hid by the weeds; and ſmall weeds being cut, are ſoon dried up by the ſun; but large weeds often take freſh root and grow again, eſpecially if rain ſhould fall ſoon after, and then the weeds will grow the faſter for being ſtirred; therefore it is not only the beſt method, but alſo the cheapeſt huſbandry, to begin cleaning early in the ſpring, and to repeat it as often as the weeds are produced.

The firſt ſummer, while the plants are young, it will be the beſt way to peform theſe hoeings by hand, but afterwards it may be done with the hoe-plough; for as the rows are four feet aſunder, there will be room enough for this plough to work; and as this will ſtir and looſen the ground, it will be of great ſervice to the plants; but there will require a little hand-labour

Digitized by Google

where the plough is uſed, in order to deſtroy the weeds, which will come up in the rows between the plants; for theſe will be out of the reach of the plough, and if they are not deſtroyed, they will ſoon overgrow and bear down the young plants.

After the plants have grown two years, it will be proper to draw out ſome of them, where they grow too cloſe; but in doing this, great care ſhould be had not to injure the roots of thoſe left; for as the plants which are drawn out are only fit for plantations deſigned for pleaſure, ſo theſe ſhould not be ſo much regarded in their being removed, as to ſacrifice any of thoſe which are deſigned to remain. In the thinning of theſe plantations, the plants may at the firſt time be left about one foot aſunder, which will give them room enough to grow two or three years longer, by which time it may be eaſy to judge which are likely to make the beſt trees; therefore theſe may be then fixed on as ſtandards to remain, though it will be proper to have a greater number at this time marked than can be permitted to grow, becauſe ſome of them may not anſwer the expectation; and as it will be improper to thin theſe trees too much at one time, ſo leaving double the number intended at the ſecond thinning will not be amiſs. Therefore, if they are then left at about four feet diſtance in the rows, they will have room enough to grow three or four years longer; by which time, if the plants have made good progreſs, their roots will have ſpread over the ground, therefore it will be proper to take up every other tree in the rows. But by this I do not mean to be exact in the removing, but to make choice of the beſt plants to ſtand, which ever rows they may be in, or if they ſhould not be exactly at the diſtance here aſſigned; all that is deſigned here, is to lay down general rules, which ſhould be as nearly complied with as the plants will permit; therefore every perſon ſhould be guided by the growth of the trees in the performance of this work.

When the plants have been reduced to the diſtance of about eight feet, they will not require any more thinning. But in two or three years time, thoſe which are not to remain will be fit to cut down, to make ſtools for under-wood; and thoſe which are to remain, will have made ſuch a progreſs as to become a ſhelter to each other; for this is what ſhould be principally attended to, whenever the trees are thinned; therefore in all ſuch places as are much expoſed to the wind, the trees ſhould be thinned with great caution and by ſlow degrees; for if the air is let too much at once into the plantation, it will give a ſudden check to the trees, and greatly retard their growth; but in ſheltered ſituations, there need not be ſo great caution uſed as in thoſe places, for the plants will not be in ſo much danger of ſuffering.

The diſtance which I ſhould chuſe to allow to thoſe trees which are deſigned to remain for timber is, from twenty-five to about thirty feet, which will not be too near, where the trees thrive well; in which caſe their heads will ſpread, ſo as to meet in about thirty or thirty-five years; nor will this diſtance be too great, ſo as to impede the upright growth of the trees. This diſtance is intended, that the trees ſhould enjoy the whole benefit of the ſoil; therefore, after one crop of the under-wood, or at the moſt two crops are cut, I would adviſe the ſtubbing up the ſtools, that the ground may be entirely clear, for the advantage of the growing timber, which is what ſhould be principally regarded; but in general, moſt people have more regard for the immediate profit of the under-wood than the future good of the timber, and frequently by ſo doing ſpoil both; for if the under-wood is left after the trees are ſpread ſo far as that their heads meet. the under-wood will not be of much worth; and yet, by their ſtools being left, they will draw away a great ſhare of nouriſhment from the timber-trees, and retard them in their progreſs.

The ſoil in which the Oak makes the greateſt progreſs, is a deep rich loam, in which the trees grow to the largeſt ſize; and the timber of thoſe trees which grow upon this land, is generally more pliable than that which grows on a ſhallower or drier ground, but the wood of the latter is much more compact and hard. Indeed there are few ſoils in England, in which the Oak will not grow, provided there is proper care taken in their cultivation, though this tree will not thrive equally in all ſoils; but yet it might be cultivated to a national advantage upon many large waſtes in ſeveral parts of England, as alſo to the great profit of the eſtates where theſe tracts of land now lie uncultivated, and produce nothing to the owner. And ſhould the preſent temper of deſtroying the timber of England continue in practice ſome years longer, in the ſame degree which it has for ſome years paſt, and as little care taken to raiſe a ſupply, this country which has been ſo long eſteemed for its naval ſtrength, may be obliged to ſeek for timber abroad, or be content with ſuch a naval ſtrength, as the poor remains of ſome frugal eſtates may have left growing; for as to the large foreſts, whence the navy has been ſo long ſupplied, a few years will put an end to the timber there; and how can it be otherwiſe, when the perſons to whoſe care theſe are committed, reap an advantage from the deſtruction of the timber?

Before I quit this ſubject, I muſt beg leave to take notice of another great evil, which is of ſo much conſequence to the public, as to deſerve their utmoſt attention; which is, that of cutting down the Oaks in the ſpring of the year, at the time when the ſap is flowing. This is done for the ſake of the bark, which will then eaſily peel off; and for the ſake of this, I think, there is a law, whereby people are obliged to cut down their timber at this ſeaſon. But by ſo doing, the timber is not half ſo durable as that which is felled in the winter, ſo that thoſe ſhips, which have been built of this ſpring-cut timber, have decayed more in ſeven or eight years, than others which were built with timber cut in winter, have done in twenty or thirty. And this our neighbours the French have experienced, and therefore have wiſely ordered, that the bark ſhould be taken off the trees ſtanding, at the proper time, but the trees are left till the next, and ſometimes until the ſecond winter, before they are cut down; and the timber of theſe are found to be more durable and better for uſe, than that of any trees which have not been peeled.

[Mr. Boutcher's method of raiſing Oaks is this.—Having provided acorns in the autumn, gathered from the handſomeſt and moſt vigorous trees, in fair weather, ſpread them in an airy covered place, and turn them frequently till quite dry; then mix them with ſand, or light looſe earth, and let them be protected from vermin, froſt, and moiſture till about the middle of february.

Having then tried the goodneſs of your ſeeds in water, make ſhallow drills acroſs the ground, which has been well prepared by clean digging and raking, at eighteen or twenty inches diſtance: in theſe drop the acorns about two inches aſunder, covering them two inches deep with the back of a rake; keep the ground, when raked ſmooth, clean and mellow during the ſummer.

At the beginning of april cut them under ground, and let them remain till the ſpring after. Then, as ſoon as their buds begin to ſwell, take them carefully up, without tearing their roots or fibres: ſeparate the ſtraight free-growing plants from the crooked and ſhrubby; ſhorten any downright or bruiſed roots, but be very ſparing of the ſmall fibres: plant the ſtraight and crooked trees ſeparate, in rows two feet aſunder and nine inches in the row. Take up few at a time, that they may not be too long out of the ground: four men will quickly diſpatch a great number, one in taking up, a ſecond in pruning, and two in planting.

If the land be good, and the ſeaſons favourable, the ſtraight plants may be removed in two years; otherwiſe they may continue three ſeaſons.

The crooked and bruſhy trees having ſtood two years, muſt be cut over near the ground, and remain two years longer: as ſoon as their ſhoots are four or five inches long, pinch off all but the moſt promiſing one.

Another method of raiſing theſe trees is, to ſow the acorns on beds in rows ſeven or eight inches aſunder,

Digitized by Google

and two or three inches in the row, covering them the uſual depth, and letting them remain only one year. Remove them the following ſpring, and having ſhortened their tap-roots, lay them in rows, cut down perpendicular by the ſpade, eighteen inches aſunder, and eight or nine inches in the row; here they may continue two years.

Then remove them again, ſeparating the ſtraight from the crooked, and plant them in rows, two feet and a half aſunder, and one foot diſtant in the row; the ſtraight plants to continue three years, and the crooked, if they have grown freely, to be cut over in one year; if not, in two years; and here they ſhould remain three years longer.

Mr. Boutcher prefers ſpring ſowing, becauſe ground, well trenched and dug, mellowed by the winter, and laid down ſweet and looſe in ſpring, muſt nouriſh the plants much better than that laid down in autumn, and battered by winter rains.

He is alſo very much againſt dibbling, on this and all other occaſions, eſpecially for the Oak and the nut-bearing trees, particularly on ſtrong land. He obſerves very well, that if the holes made by a dibble prove not their immediate grave, they will at leaſt be their priſon.

If trees are to be tranſplanted large, they muſt be removed once or twice more: remaining from four to ſix years after the firſt removal, and ſix or ſeven after the ſecond, by which time they will be twenty feet high. They may be removed with more ſafety, and grow more freely, when tranſplanted in the ſpring than in autumn.—But this method of Mr. Boutcher's will anſwer only for ornamental trees, or where they are wanted for immediate ſhelter, or to fill up gaps near the manſion.

A gentleman of conſiderable experience in this matter, greatly doubts whether a ſingle planted Oak was ever carried into the dock-yard for the purpoſe of ſhip-building. Tranſplanted Oaks, in his opinion, ſcarcely ever make thriving trees; the tap-root, which is deſtroyed in moving, ſeeming to be neceſſary towards extending the plant to its fulleſt ſize. Whoever therefore tranſplants Oaks, would do well to ſet ſome acorns among them [l].

There is little doubt but that in raiſing Oak for timber, it is far better to ſow the acorns in the ſpot finally deſtined for the wood, than to raiſe the trees in a nurſery, and tranſplant them. But it is a doubt, ſays Mr. Gilpin, whether it be more judicious to ſow the acorn, after incloſing and grubbing the ground; or, without either operation, in the midſt of Thorn-buſhes and Hollies, which will defend the ſapling from cattle, till it be able to ſtand alone; and will draw it in its early ſtate to much quicker maturity, than it can arrive at without ſuch ſhelter. The latter way is not ſo ſure; but much greater quantities may be ſown at a ſmaller expenſe; and if one tenth of the acorns ſucceed, the ſaving is great on an equal quantity of timber [k].

In waſtes, if acorns were to be ſown unprotected by buſhes, however they may be guarded by the firſt planter, they require ſo many renewals of fences and guardians, that they have little chance, before they are neglected, of arriving at a height ſufficient to withſtand the attacks of cattle, eſpecially when we conſider how difficult it is to preſerve fences from the lawleſs depredations of cottagers inhabiting the borders of foreſts [l]. If the ground however be incloſed and not grubbed, the acorns ſown among the buſhes have thus a double chance of eſcaping.

The late Duke of Bedford, when he was Lord Warden, was very intent on raiſing timber in this fortuitous manner. He merely incloſed, and left it to chance to fill his incloſures. But Mr. Gilpin ſays, he does not find that any of them ſucceeded. He recommends to incloſe, and here and there to grub a ſpot and ſow two or three acorns in it, taking ſome little care of them afterwards. This he ſuggeſts, as perhaps the moſt certain, and the leaſt expenſive way of raiſing timber [m].

[l] Gentl. magaz. 55. 109. & 57. 860. Tho. White, Eſq.
[k] For. ſcen. [l] White in Gent. magaz. 57. 860.
[m] Foreſt ſcenery, 2. 35.

Mr. Nichols, whoſe good ſenſe and experience demand our reſpect and confidence, affirms that nothing aſſiſts more in the propagation and preſervation of timber than thorns and buſhes, eſpecially where there are no fences to keep off cattle. Under-wood, ſays he, never fails to bring a ſtock of timber on a favourable ſoil: and the deſtruction of buſhes in lands not incloſed, will aſſuredly prevent a ſucceſſion of timber, by depriving the young plants of their nurſes, and leaving the acorns which are caſually dropped expoſed to various enemies. The conſtant cutting therefore of under-wood by the keepers in foreſts, under pretence of browſe for the deer, is attended with the moſt miſchievous conſequences to the growth of timber. The unlimited mowing of Fern is alſo extremely injurious to the growth of timber; for the Fern ſhades the roots, and keeps the young plants moiſt and cool: and by cutting it up, the young trees are cut up with it as ſoon as they ariſe.

Making plantations therefore without any previous preparation, being the cheapeſt, and anſwering the purpoſe extremely well, is recommended by Mr. Nichols [n].

This is certainly a very reaſonable mode of proceeding in foreſts, and waſtes full of buſhes: and Mr. Nichols has invented a very good inſtrument for introducing and planting acorns among the buſhes. But in raiſing a new wood, it muſt be much more effectual to prepare and clean the ground well, and to ſet the acorns in drills, that the young plants may be kept clean by horſe-hoeing till they can bid defiance to weeds.

With reſpect to the compariſon between ſown and planted Oaks, Mr. Plampin, of Chadacre in Suffolk affirms, that the latter are ſo inferior to the former, as to induce him to give a general condemnation of planting for timber [o].

Hanbury joins his teſtimony to that of Miller, in favour of raiſing Oaks from the acorn, without removing. They grow ſlowly, ſays he, on account of the tap-root ſtriking deep into the ground, where there is leſs nouriſhment; but when they arrive at timber, they are the beſt trees, being generally fuller at heart, and more compact, ſtrong and laſting [p].

Mr. Marſhall would reconcile the diſpute about ſowing and planting, in ſome meaſure thus: Where the ſtrength of the land lies in the ſubſtratum, while the ſurface ſoil is of an ungenial nature, *ſow*, in order that the roots may ſtrike deep: but on the contrary, when the top ſoil is good, and the bottom of an oppoſite quality, *plant*, and thereby give the roots the full enjoyment of the productive part of the ſoil; or, under theſe laſt circumſtances, ſow, and *tap* the young plants as they ſtand, and thereby check their downward tendency, as well as ſtrengthen their horizontal roots [q].

Lewis Majendie, of Hedingham Caſtle, Eſſex, Eſq. in his plantations of Oak, removed two-year old ſeedlings with the greateſt care from the ſeed-bed, by undermining the roots, ſo as to bring them up undamaged and entire: the ſubſoil being a rich tender loam, holes were bored into it with an iron inſtrument uſed for fixing hop-poles: great caution was uſed that each ſeedling ſhould have a hole ſuitable to the length of its tap-root, which was ſet upright, with care not to double it: the tap-roots were from eighteen to thirty-ſix inches in length.

By this method, Mr. Majendie avoided giving his young Oaks two checks, which they have in the common way of tranſplanting; and by planting them out finally at ſo early an age, they would the ſooner recover their removal. By preſerving the tap-roots alſo, he planted his trees as much as poſſible in a natural ſtate; which is a reaſonable practice, as he remarks, until the queſtion ſhall be decided, whether it is beſt, in order to procure timber of the firſt quality, to ſow acorns where they are to remain, or to tranſplant them from the ſeminary or nurſery.

With a view to a compariſon between young Oaks planted with their roots entire, and thoſe whoſe roots had been tapped, Mr. Majendie, in december, 1786, ſelected from among his ſeedlings, twenty-four of the ſtraighteſt, three feet ſix inches in length: of theſe he planted twelve with entire roots; and the remaining twelve at the ſame time and diſtance, taking off eighteen inches from their tap-roots, and leaving nine inches. In december 1791, he took up trees of each ſort, and found that in the former, the tap-root had acquired a regularity of thickneſs in its general growth, and that its lateral ſhoots were moſtly fibrous: and that on the other hand the mutilated trees had thrown out a number of thick woody horizontal roots near the place where the tap-root was ſhortened; after which the root reſumed its natural downward tendency, with a regularity that might almoſt induce an idea that the root had never been divided.

Theſe trees were fifteen inches in height from the ground, when they were planted: five years after the following were the meaſurements of each.

Oak planted with an entire root.			Oak planted with a tapped root.		
	Feet.	In.		Feet.	In.
Extreme height from the bottom of the tap-root - - -	11	2½	——	10	3
Height from the ground - -	7	7	——	6	9
Circumference cloſe to the ground - -	0	6¼	——	0	6½

As this ingenious gentleman purpoſes from time to time, by digging up others of theſe trees, to obſerve the comparative progreſs of them, the public will hereafter be enabled to form ſome judgment on this ſubject. It were to be wiſhed that Mr. Majendie had ſown ſome acorns in his plantations, in order to have compared the trees from thoſe with the planted ones.

In raiſing Oaks for timber, draining ſhould be well attended to; nothing contributing more to their growth and health, than keeping the land dry, if it is in the leaſt inclinable to be ſwampy.

The Oak flouriſhes beſt and grows quickeſt in a rich deep loam, and the wood of ſuch trees is of the firmeſt and beſt texture [s].

It will alſo grow exceedingly well on clays and ſandy ſoils, and on theſe laſt the fineſt-grained timber is produced. Many fine trees of this texture may be ſeen on Nottingham foreſt, particularly at Welbeck [t].

The Oaks of Temple and Blackmoor in Selborne pariſh have furniſhed much naval timber; the ſoil a wet ſandy loam. The trees on the freeſtone grow large, but are what workmen call *ſhakey*, and ſo brittle as often to fall to pieces in ſawing [u].

Mr. Speechly affirms that it matters not from what ſort of tree the acorns are gathered, provided they are good. Mr. Nichols on the contrary adviſes the choice of acorns from the moſt healthy trees. The latter had ſeen the bad conſequences of not attending to this choice, in the New Foreſt, where ſome of the incloſures were planted at the beginning of this century with acorns taken from a variety known there by the name of the *Durmaſt Oak*, which is of a freer growth than the true Oak, and attains as large a ſize, but in the quality of the timber is far inferior [x].

There can certainly be no harm in taking the acorns from flouriſhing healthy trees; and at any rate they ſhould not be gathered until they are full ripe, and beginning to fall. If the quantity wanted be not great, ſuch as fall of themſelves, or may eaſily be ſhaken from the trees ought to be preferred: theſe I have never known fail to grow.

Mr. Evelyn ſays, that ſix buſhels of acorns will plant an acre, at the diſtance of one foot from each other. Two buſhels therefore, which ſome recommend as ſufficient, muſt be much under the mark; unleſs the acorns are ſown with the ſeeds of other trees, for a mixt wood or coppice.

One of the moſt eſſential things to be obſerved in the management of Oak woods is the judicious thinning of them. When they are thinned ſo as to be about two feet diſtant, they may ſtand twelve or fourteen years, when every ſecond plant may be taken out and ſold for hoops or ſmall poles: only obſerving that if the ground be good, and the trees take to growing well, they will want thinning ſooner. In ſeven or eight years more the healthieſt trees muſt be marked for timber, and the others cut down for poles, and the ſtools left for under-wood [y]. In thirty years they will be uſeful for ſmall ſcantlings, ſpars, rafters, batlings, rails, props, &c. not quartered.

All this time, according to the opinion of ſome, they ſhould never on any account be touched with the knife, axe or pruning-hook. Some recommend the cutting off ſide ſhoots; others cutting them to the ground to make the better ſhoots.

This is the reaſon why, when Oaks are cut up in expectation of finding them clean timber, that a variety of rotten knots grown over with ſound wood appear in them, being the places where boughs had been cut off.

This is certainly the caſe where Oaks are advanced in growth, but in their infant ſtate it is generally allowed that they require judicious pruning.

To hack off a large bough, ſays Mr. Marſhall, from an aged tree, is a crime of the deepeſt dye in the management of timber. But what relation has this mad act to the ſalutary operation of removing a twig from the ſtem of a young growing tree, or of pruning the boughs, or even removing the leader of a tree in a youthful growing ſtate? In that caſe, the ſize of the wound and the exhauſted ſtate of the tree unite to prevent the healing, and a defect in the timber conſequently takes place: whilſt in this, the wound is inconſiderable, and the vigorous ſtate of the tree enables it to cicatrize the ſore, in a few months perhaps after the operation is performed.

By freeing the ſtems of young trees from ſide ſhoots, and by keeping their leaders ſingle, a length of ſtem is obtained; and by afterwards checking their upright growth, and throwing the main ſtrength of the head into one principal bough, by checking, not removing the reſt, a crookedneſs of timber is had; and what is equally neceſſary in ſhip-timber, a cleanneſs and evenneſs of contexture are produced. The dangerous, and too often fatal defect cauſed by the decayed ſtumps of dead ſtem boughs being overgrown and hid under a ſhell of ſound timber, a defect which every fortuitous tree is liable to, is by this provident treatment avoided: the timber from the pith to the ſap becoming uniformly ſound, and of equal ſtrength and durability.

Nothing but prejudice of the moſt inveterate kind, can reject a practice founded on the moſt obvious principles of nature and reaſon. The miſchief done to hedge-row trees by injudicious lopping, too generally obſervable, has ariſen from the practice of taking large boughs from the ſtems of aged trees; not from training young trees, during the early ſtages of their growth [z].

For more on this and other parts of this important ſubject ſee the articles TIMBER and WOODS.

The *ſtriped* variety of Oak is propagated by budding or grafting on the common ſort. It is a beautiful variegation, and may be improved by joining it to the Scarlet, Virginian, or Cheſtnut-leaved.

The more tender ſorts will be rendered more hardy, and the dwarf ones improved in ſize, by grafting or budding on the common Oak [a].

9. There is no tree more difficult to tranſplant than the *Ilex*, becauſe it runs with a downright root, and very few fibres; the acorns therefore ſhould be put into the places where they are deſigned to remain. Theſe trees ſoon make warm and lofty hedges, forty

[a] Boutcher.

of fifty feet high. To have plants for removal, either ſet the acorns in pots, or in drills two feet and a half aſunder, and three or four inches apart in the drill, on good ſoil; water them, and keep the ground clean: the ſecond ſpring, with a ſpade clear away the earth from one ſide of the plants, five inches deep, and with a ſharp knife, at that depth, cut the roots acroſs, taking care not to diſturb the plant, and then replace the earth, preſſing it gently down with your hands: this ſhould be repeated for three or four years. Theſe trees ſhould not be planted near the houſe or gardens, becauſe they make a great litter in april and may, when they caſt their leaves.

The beginning of march prepare a ſhallow box or boxes, the bottom bored with holes half an inch in diameter, and four or five inches aſunder, covered with oyſter-ſhells or broken tiles; put light rich mould in them five inches deep, on which place the acorns four inches aſunder, and cover them with two inches more of the ſame mould; place theſe boxes on a moderate hot-bed; and in ten or twelve days, when you find the earth beginning to dry, give them a very gentle ſprinkling of water, which repeat every fourth or fifth day. In a month the plants will begin to appear, when the quantity of water muſt be increaſed. In this hot-bed the boxes may remain till the beginning of july, when they may be placed in a ſhady ſheltered ſituation; having been before gradually inured to the open air. On the approach of winter, having cleared the boxes of all muſty particles, and replaced them with fine rich mould, place them under frames till the ſucceeding ſpring, covering them with glaſſes, only in violent rains and hard froſts.

When the weather is favourable in april or may, remove them to a well-ſheltered ſhady place in the nurſery, and place them on ſtones or logs of wood ſome inches above the ground. During the ſummer months let them be regularly watered; and in the autumn they may again be put under a frame, to be covered in caſe of a ſevere winter.

The beginning of april following the plants muſt be taken out of the boxes, when from the interruption the roots have met with, they may be taken up by a trowel, with earth adhering to them. This being done, without wounding the ſmalleſt fibre if poſſible, put them in penny pots filled with rich looſe mould; plunge the pots in a moderate hot-bed for ſix weeks or two months. Harden them gradually, and remove the pots to a north border during the remainder of the ſummer.

Having ſtood two years in the pots, they may be taken out, and planted where they are deſigned to remain, or in the nurſery two or three years more [b].

DESCRIPTIONS, *&c.*

1. This has the habit of Minuartia montana, but it is ſmaller and more brittle. The head of flowers is more obſcurely four-cornered, and very eaſily parts from the ſtem. Bractes briſtle-ſhaped, erect, hooked outwards at the tip, and adhering to the clothes. Seed one, compreſſed, roundiſh. Colour of the plant whitiſh. The ſtructure of the flowers, as well as the habit, is the ſame as in Minuartia; but this having ſingle, and that many ſeeds, their genera are diſtinct. It is an annual plant, and a native of Spain [c].

2. Root fibroſe, perennial. Stem ſtiff, dichotomous, a ſpan high, round, filiform, erect. Leaves oppoſite, lanceolate-ovate, quite entire, with duſky ſpots ſcattered over them on each ſide. Stipules in pairs on each ſide, acute, membranaceous. Flowers ſubpeduncled, ſmall, green, from each diviſion. Calyx five-parted, with bluntiſh, ſomewhat arched leaflets. The wild plant is higher, with a capillary ſtem; in cultivation it is thicker, with the leaves not at all dotted [d]. Capſule ſmall, globular, mucronate at top, membranaceous, very thin, one-celled, not opening. Seed reniform-globular, very ſmooth, ſhining, dark [e]. It differs from the preceding in having the ſtem dichotomous, with one flower at each fork, the leaves ſtipulaceous, and the habit of Linum catharticum [f]. It not only differs in its external habit, but recedes far from Q. hiſpanica in the ſtructure of the calyx and capſule; and has ſo much affinity to Arenaria and Paronychia nitida, as to differ little from them, except in the number of ſtamens [g].

3. Stem herbaceous, with filiform, very ſpreading, ſmooth branchlets. Leaves oppoſite, on very ſhort petioles, ovate, acute, entire, ſmooth, ſpreading very much, half an inch long. Axillary racemes oppoſite, terminating ones three.

Native of Japan [h].

QUITCH. See *Triticum*.]

QUICK. By this word is generally underſtood a live hedge, of whatever plants compoſed, in contradiſtinction to a dead hedge; [or rather the ſhrubs of which ſuch live hedge is formed.] In the more ſtrict ſenſe of the word it is applied to the Cratægus Oxyacantha, Hawthorn or Whitethorn; young plants or ſets of which are commonly ſold by the nurſery-gardeners under this name of Quick.

In the choice of theſe ſets, thoſe which are raiſed in the nurſery, are to be preferred to ſuch as are drawn out of the woods, becauſe the latter have ſeldom good roots: many perſons prefer them becauſe they are larger plants than are commonly to be had in the nurſery; but from long experience I have found that young plants from the nurſery always make the beſt hedges. Indeed if the ſeed or haws were ſown in the place where the hedge is deſigned to be, theſe unremoved plants would make a much ſtronger and more durable fence than thoſe which are tranſplanted; but I am aware, this practice will be generally condemned, as tedious; but if the haws are buried one year in the ground, to prepare them for vegetation before they are ſown, it will not be ſo long before this will become a good fence, as is generally imagined. Nay, from ſome trials of this kind, which I have made, I have found, that thoſe plants which have remained where they came up from ſeed, have made ſuch progreſs as to overtake, in ſix years, plants of two years growth, which were tranſplanted at the time when theſe ſeeds were ſown.

And if the hedges are raiſed from ſeed, it will not be amiſs to mix Holly berries with the Haws; and if

[b] Boëtcher. [c] Linn. ſpec. [d] Idem. [e] Gærtner. [f] Juſſieu. [g] Gærtner. [h] Thunb. jap.

Digitized by Google

ſo, theſe berries ſhould alſo be buried one year, to prepare them, ſo that then both will come up together the following ſpring; and this mixture of Holly with the Quick, will not only have a beautiful appearance in the winter, but will alſo thicken the hedge at the bottom, and make it a better fence.

But where the hedge is to be planted, the ſets ſhould not be more than three years old from the Haws; for when they are older, their roots will be hard and woody; and as they are commonly trimmed off before the ſets are planted, ſo they very often miſcarry; and ſuch of them as do live, will not make ſo good progreſs as younger plants, nor are they ſo durable; for theſe plants will not bear tranſplanting ſo well as many others, eſpecially when they have ſtood long in the ſeed-bed unremoved.

The method of planting, as alſo of plaſhing and pruning of theſe hedges, having been fully explained under the article of HEDGES, I ſhall not repeat that here, but ſhall only beg leave to add the method which is preſcribed by Thomas Franklin, Eſq. which he had long practiſed in planting of theſe hedges, which is as follows:

He firſt ſet out the ground for ditches and Quick ten feet in breadth; he ſubdivided that, by marking out two feet and a half on each ſide (more or leſs at pleaſure) for the ditches, leaving five in the middle between them; then digging up two feet in the midſt of thoſe five feet, he planted the ſets in; which although it required more labour and charge, he ſays, he ſoon found it repaid the coſt. This done he began to dig the foſſes, and to ſet up one row of turfs on the outſide of the ſaid five feet; namely, one row on each ſide thereof, the green ſide outmoſt, a little reclining, ſo as the Graſs might grow.

After this, returning to the place he began at, he ordered one of the men to dig a ſpit of the under-turf mould, and lay it between the turfs placed edgewiſe, as before deſcribed, upon the two feet, which was purpoſely dug in the middle, and prepared for the ſets, which the planter ſet with two Quicks upon the ſurface of the earth almoſt upright, whilſt another workman laid the mould forwards about twelve inches, and then ſet two more, and ſo continued.

This being finiſhed, he ordered another row of turfs to be placed on each ſide upon the top of the former, and filled the vacancy between the ſets and turfs as high as their tops; always leaving the middle, where the ſets were planted, hollow, and ſomewhat lower than the ſides of the banks by eight or ten inches, that the rain may deſcend to their roots; which is of great advantage to their growth, and by far better than by the old method, where the banks are made too much ſloping; and the roots of the ſets are ſeldom wetted, even in a moiſt ſeaſon, the ſummer following; but if it prove dry, many of the ſets, eſpecially the late planted, will periſh; and even few of thoſe that had been planted in the beginning of april (the ſummer happening to be ſomewhat dry) eſcaped.

The planting being thus advanced, the next care is fencing, by ſetting a hedge of about twenty inches high upon the top of the bank on each ſide thereof, leaning a little outwards from the ſets, which will protect them as well (if not better) than a hedge of three feet or more, ſtanding on the ſurface of the ground; for as theſe are raiſed with the turfs and ſods about twenty inches, and the hedge about twenty inches more, it will make three feet four inches, ſo as no cattle can approach the dead hedge to prejudice it, unleſs they ſet their feet in the ditch itſelf, which will be at leaſt a foot and a half deep; and from the bottom of the foſs to the top of the hedge, about four feet and a half, which they can hardly reach over to crop the Quick, as they might in the old way; and beſides, ſuch a dead hedge will endure a year longer.

He ſays, he had a hedge which had ſtood five years; and though nine or ten feet were ſufficient for both ditches and banks, yet where the ground is but indifferent, it is better huſbandry to take twelve feet, which will allow of a bank at leaſt ſix feet broad, and gives more ſcope to place the dead hedges farther from the ſets, and the ditches being ſhallow, will in two years time graze.

As to the objection, that taking twelve feet waſtes too much ground, he affirms, that if twelve feet in breadth be taken for a ditch and bank, there will no more ground be waſted than by the common way; for in that a Quick is rarely ſet, but there are nine feet between the dead hedges, which is entirely loſt all the time of fencing; whereas with double ditches, there remain at leaſt eighteen inches on each ſide where the turfs were ſet on edge, that bear more Graſs, than when it lay on the flat.

But, admitting it did totally lay waſte three feet of ground, the damage would be very inconſiderable; ſince forty perches, in length, two hundred and twenty yards, will make ſeven poles and a half; which at 13s. and 4d. the acre, amounts not to 7d. ½ per annum.

Now that this is not only the beſt, but cheapeſt way of Quick-ſetting, will appear by comparing the charge of both.

In the uſual way, the charge of a three feet ditch is 4d. per pole, the owner providing ſets; if the workman finds them, he will have for making the ſaid ditch and ſetting them, 8d. per pole; and for hedging, 2d. that is, for both ſides, 4d. the pole; which renders the charge of hedging, ditching, and ſets, 12d. the pole; that is, for forty rods in length 40s.

Then one load of wood out of the copſe coſts (with the carriage, though but two or three miles diſtance) 10s. which will ſeldom hedge above eight poles (ſingle hedge;) but allowing to do ten, to fence forty poles, there muſt be at leaſt eight loads of wood, which coſts 4l. making the whole expenſe for ditching, fencing, and ſetting forty poles, to be 6l. reckoning with the leaſt; for ſcarce any will undertake to do it for leſs than 3s. 6d. per pole, and then the forty poles coſt 7l.

Whereas with double ditches, both of them, with the plants included, will be done for 8d. the pole, and the huſbandman get as good wages as with the ſingle ditch (for though the labour about them is more, yet the making the table is ſaved,) which coſts 1l. 6s. 8d. and the hedges being low, they will make better wages at hedging for a penny a pole, than at 2d. for common hedges, which comes to 6s. 8d. for hedging forty poles on both ſides. Thus one load of wood will fence thirty poles at leaſt, and forty hedged with two thirds of wood leſs than in the other way, and coſt but 1l. 6s. 8d. which makes the other whole charge of ſets, ditching, fencing, and wood, but 3l.

[At preſent, garden Quick, or Whitethorn raiſed by nurſery gardeners is generally uſed in fencing new incloſures. It is ſold at from 7s. to 10s. the thouſand. According to Mr. Marſhall's account a gentleman near Tamworth was the firſt who ventured to plant garden Quick on a large ſcale, and his ſucceſs ruined the buſineſs of collecting the plants from woods. Autumnal planting generally ſucceeds beſt; eſpecially if the ſoil be light, the ſituation dry, and the following ſpring and ſummer ſhould prove dry alſo.

The methods of planting Quick are various. Some put the plants into a broad flat mound; generally planting two rows, ten or twelve inches apart, and at the like diſtance from the brink of the trench, by the ſide of which they are planted. The reaſon given for this mode of planting is, that a deep ditch makes a high heavy bank, and this overloads the roots. There is ſome truth in this reaſoning. Plants never thrive ſo well as on level ground, provided they are not incommoded by ſtanding water. Yet we ſee that hedges may be raiſed with ſucceſs in front of a high bank, and that its advantages are by no means equal to the advantage gained by a deep ditch and high bank, as a defence to the riſing hedge. Two rows of oak poſts with three, or in ſome places only two rails, are the common guard; and a ſmaller poſt, (provincially a pile,) ſhould be nailed to the rails in the middle between the principal poſts to ſtrengthen the rails, which will otherwiſe eaſily be diſplaced or broken. All this is done at an expenſe at leaſt double that of a deep ditch and banklet on one ſide, and a high bank and hedge

Digitized by Google

on the other. If the hedge be planted behind a ſhelf of ſufficient width, and part of the mould of the ditch be applied in forming a banklet on its outer brink, the load incurred by the remainder is little, if any impediment to the progreſs of the young hedge.

The method of planting a Quick hedge in this manner is thus. The ditch is an equilateral triangle, each ſide or ſlope, as well as the width being forty-nine inches and a half or a quarter of a rod. The bank, on the fence ſide is formed of the three firſt ſpits of mould; a banklet, as a guard to the outer brink of the ditch, of the fourth ſpit and the pointing; which laſt is raiſed with a narrow-pointed draining tool. At each rod an oakling may be laid in with the Hawthorn plants. The planting of theſe is performed thus. The firſt ſpit forms the bottom or foundation of the bank; over this the ſecond ſpit being ſpread evenly, the face is adjuſted and the top levelled; and a line being ſtretched a foot from the angle of the mound, a narrow trench is opened behind it, by chopping the ſpade down to the firſt ſpit, and drawing back the looſe mould. In this trench the plants are ſet, from four to ſix inches apart, nearly upright, and their roots bedded in the fineſt of the mould; caſting the third ſpit behind the line of plants. The guard in front is a ſharp ridge or banklet, formed on the oppoſite brink of the ditch, with the fourth ſpit and the pointing. Behind is a low ſtiff hedge, ſet on the bank formed by the third ſpit; the edders well beaten down with a beetle, and the ſtakes driven to within a hand's breadth of the edders; and the face trimmed to prevent the ſpray from dripping upon the plants. Laſtly the back of the bank is made up with a ſufficient ſlope to ſtand firmly, and may be ſown with Ray-graſs and white Clover. The expenſe of ſuch a fence as this was not quite 2s. 3d. a rod, not 5d. a yard [i]. A low dead hedge upon the ridge in front will be a great additional ſecurity to the Quick.

Quick hedges are raiſed in Norfolk without poſt or rail at leſs than two-pence halfpenny a yard; whilſt in many parts of the kingdom, where two rows of poſts and rails are in common uſe, 8d. to 1s. a yard is the uſual expenſe. But their mode of planting is bad, for they lay in the Quickſets near the top of the bank, with their heads pointing into the ditch, and the rains waſhing away the bank, the ſets are often found at the bottom of the ditch [k].

The late Mr. Bakewell planted one row of Quick at a foot from ſet to ſet, and making his ditch, laid the earth which came out of it to form a bank on the ſide oppoſite to the Quick. In the common method, the bank is made on the Quick ſide above it. Reaſons are not wanting to induce a preference of this method. The plants grow only in the ſurface earth, uncovered from the atmoſphere, which muſt be a great advantage; whereas in the uſual way of planting, that earth which is always the beſt, is loaded with a thick covering, obliquely, of the earth out of the ditch. If the roots ſhoot in the beſt ſoil, they will be out of the reach of the influence of the air, the conſequence of which is, they cannot have ſo large a ſpace of that earth, as if ſet upon a flat. The way to have a Quick thrive in the beſt manner poſſible, is to ſet it on the ſurface, without any ditch or trench, that cuts off half its paſture. But if a ditch be neceſſary, the next beſt way muſt ſtill be to keep it on the flat ſurface; and the worſt way to cover up that ſurface, by loading it with dead earth out of a trench.

The fences, with a double poſt and rail, one on the outſide of the bank, the other on the outſide of the Quick are very expenſive, and together with the ditch and bank, altogether occupy a ſpace, which on good land is enormous. It ſeldom happens that a poſt and rail is neceſſary on the bank ſide; commonly a few thorns laid againſt the bank are a ſufficient fence; and on the other ſide, if the land be kept in tillage, no guard is wanted, as the cropping of the Quickſets in the autumn does them little injury for the two firſt years, after which they ſhould be cut off; and after this, brouſing in the autumn does little injury; but in the ſpring it ſhould be carefully guarded againſt, by ſome temporary fence [l].

This cheap mode of fencing might perhaps ſuffice, if the landlord had an agent in whom he could confide; always on the ſpot, or if the tenant were to make and keep up the fences. But unleſs horſes, cattle and ſheep are effectually kept from the Quick, the expenſe of planting will be in a manner thrown away; and it is ſeen by fatal experience that tenants will not attend to the preſervation of Quick, although a good live fence is ſo much to their advantage.

In poor ſandy ſoils, where the growth of Quick-hedges is ſlow, where they are liable to the depredations of ſheep, and where, by reaſon of the looſeneſs of the ſoil, the ditch is little or no defence, Brambles have been recommended to raiſe Quick hedges in the ſhorteſt time, and at the leaſt expenſe. Mr. Le Blanc informs us, that the idea of the utility of Brambles for this purpoſe firſt ſtruck him, by obſerving ſeveral incloſures made in a blowing ſand, on each ſide of a narrow field-road, along which a large flock of ſheep was frequently driven: on one ſide of the road the bank was planted with Brambles mixed with the White-thorn, and a dead hedge placed on the top; this has never ſince been renewed, and the fence became a tolerably good one. The Bramble, which is a very faſt grower, not only defends the young Quick from the ſheep, but likewiſe by twiſting itſelf through the dead hedge ſtrengthens it, and prevents it from being broken down or carried off. On the other ſide of the road, the bank was planted at the ſame time, and in the ſame manner, but with White-thorn only. The dead hedge has been renewed ſeveral times, and there is no probability that the Quick will ever make a fence. From this hint Mr. Le Blanc made an improvement, by planting two rows on the bank; the lower one of Bramble only, the upper one of White-thorn only. He tried this method in 1781 and the following year, and both fences in ſeptember 1784 were much more promiſing than he could have expected them to be, if planted with White-thorn only [m].

Quick does well on good ſtrong land; but on dry, gravelly or poor ſoils it ſeldom proſpers. The reaſons of this are, firſt, that the ſets are put too low or flat on the ſurface; whence their roots only occupy a little depth of the ſoil. Secondly, when ſet higher, they are generally too near the ſlope of the bank; hence they do not receive the benefit of the rain. To remedy theſe inconveniences, two lines may be marked out, twelve feet from each other; from three feet within each line the upper part of the ſoil is to be taken, and caſt into the centre of the ſpace, ſo as to form a flat bed, three feet broad, in the middle of which the Quicks are to be planted; the remaining eighteen inches on each ſide is to be filled up with earth, gravel or ſand, taken out of the ditches: this extends the bed to five feet, allowing ſix inches for the ſlope of the bank: the Quicks planted in this body of ſoil, will find ſufficient nouriſhment, before the tap-root reaches the barren gravel below, and the earth thus placed, (eſpecially if the bed be laid concave, or ſloping a little to the middle,) will retain ſufficient moiſture to nouriſh the plants, and they will ſoon form a fence. By raiſing the bank on each ſide at pleaſure, the plants may be defended from ſharp winds, or the ſea-air. The ſpace required for ſuch a fence is no great object on low-priced land, and a good thriving hedge is an ample compenſation [n].

On ſuch dry ſoils, Furze, called alſo Gorſe and Whins, is eaſily propagated from ſeed, grows faſt, and when ſown in a triple row, makes a very formidable fence; but it is liable to be completely cut down by a ſevere winter. No dependance therefore can be placed on it, except as a temporary defence, during the minority of the White-thorn [o].

Nurſing young Quick hedges, by proper training and weeding, is too much neglected. The luxuriant

ſide-

ſide-ſhoots ought to be taken off, and thereby the upright growth of the plant promoted, by training it to a ſingle ſtem.

One advantage of this method is that of rearing every plant with a degree of certainty; the tops being in this operation attended to as well as the ſtems: thoſe of the ſtronger plants being leſſened, to give head-room to the weaker. Another great advantage, eſpecially on a ſheep-farm, is that of getting the young plants out of harm's way. Sheep are dangerous enemies to young Quick; and every expedient to guard againſt them deſerves a trial. Strong plants, judiciouſly placed, and trained in this manner, may, with a degree of certainty, be got out of the reach of ſheep in three or four years. The pruning ſhould be done in winter or ſpring, whilſt the ſap is down [p].

Young Quick hedges ſhould be kept conſtantly clean from weeds; and, if foul, ſhould be hoed and weeded by hand twice in the year. If the weeds are numerous and ſtrong, ſo as to outgrow the ſhoots, theſe are drawn up weak and are much injured. Root or perennial hedge-weeds ſhould be carefully eradicated, as the common creeping Thiſtle (Carduus arvenſis,) Docks, Nettles, Bindweeds (Convolvulus ſepium and arvenſis,) Fern: in moiſt ſituations, the Meadow-ſweet, Willow-herbs, &c. but eſpecially the Perſicarias, which are almoſt certain ſuffocation to weak plants, the firſt and ſecond years, if not repeatedly removed by hand. Graſſes in general may be deſtroyed by the hoe; but ſcarcely any art can free young hedge plants from Quick-graſs or Couch; which ought therefore, at almoſt any coſt to be deſtroyed before the Quick is planted. Cleavers (Galium Aparine, provincially Haireff) and other climbing plants, are a burden to the taller more upright ſhoots. Biennial and annual weeds, ſuch as all the Thiſtles, except that mentioned above, Sowthiſtles, the Hawkweeds (provincially Goulds,) Cow-weed, and ſeveral other umbelliferous plants (provincially Keckſies,) Charlock, ſeveral of the wild Vetches, and a variety of ſmall weeds, which rob the plants of their nouriſhment, ought to be cut off with the hoe, ſo often as they riſe, or at leaſt before they come to ſeed [q]. Great care is requiſite in weeding young hedge-ſhoots. They are very brittle, and roughneſs in handling is liable to break them off at the ſtub. They ought not to be pulled aſide, nor weeded over-hand; but the weeds ſhould be drawn out at the bottom, by putting the hand, or the fingers in neatly between the ſtubs [r].

For farther particulars on this ſubject ſee Mr. Marſhall on planting, and our articles CRATÆGUS, FENCES, HEDGES.

DESCRIPTION, *&c.*

Branches round, pubeſcent. Leaves oppoſite, petioled, cordate or ovate, quite entire. Stipules none. Spikes terminating and axillary peduncled, with ovate-oblong oppoſite bractes, and oppoſite flowers, the ſize of thoſe of Daphne, with the calyx filiform, pubeſcent on the outſide [t].

Loureiro deſcribes it as a large unarmed ſhrub, with a thick, almoſt upright ſtem, and climbing branches: the flowers white tinged with red, in terminating corymbs. Drupe oblong, attenuated at both ends, acutely five-cornered, an inch long.

Native of the Eaſt Indies, China and Cochinchina. It differs according to ſeaſon and ſituation, but theſe varieties make one ſpecies.

QUIVISIA of Juſſieu, is the ſame genus as Quiviſia of Cavanilles; and is taken up by Gmelin under the name of Gilibertia [u].

   Leaves ſerrate, leaflets oblong acute, flowers in racemes.

DESCRIPTIONS, *&c.*

Theſe are climbing plants, by means of the ſtem twiſting towards the left. The root is tuberous; and the flowers in axillary ſpikes or racemes. They are natives of the Weſt Indies.

1. Native of Domingo.

2. Leaves oblong, acuminate, netted. Flowers in racemes [x]. Capſule like parchment, of a ſilky-tawny colour; the ſurface of the wing, from the place of the ſeed, radiately ſtriated. Seed ſmooth, ſhining, of a deep cheſtnut colour, faſtened to the anterior angle of the cell, below the riſe of the flower [y].—Native of South America.

3. Stem filiform, twining, looſe, round, ſubdivided, ſmooth. Leaves alternate, about a ſpan in length, entire, three-nerved, veined, ſmooth. Petioles twiſted in the ſame direction with the ſtem, ſmooth, red. Racemes filiform, in pairs, the length of the leaves, pendulous, many-flowered: flowers polygamous, very ſmall, ſubſeſſile, red: pedicels alternate, directed one way, five or ſix-flowered. Bractes very minute, acute, blood-red, under the flowers. Segments of the calyx, in both flowers, from upright ſpreading, blunt. Anthers in the male ſubſeſſile, ſmall, placed in three rows ſo as to form a triangle. The hermaphrodite flowers have ſix filaments with fertile anthers; a three-cornered oblique germ, without any ſtyle, but with three minute ſtigmas. It flowers in may, and ſeeds in june. It is an annual, and is found in the drieſt coppices of Hiſpaniola, on the weſtern ſide, climbing up the tall trees.

4. Stem fruteſcent, filiform, ſubdivided: branches filiform, leafy, ſmooth. Leaves ſomewhat remote, entire, veined, ſmooth on both ſides. Petioles often the length of the leaves, round, ſmooth. Racemes axillary, ſeveral, longer than the leaves, filiform, ſubflexuoſe, many-flowered. Flowers dioecous: the males in compound racemes, with alternate racemelets; the females in ſimple racemes, with the flowers moſtly directed one way, and pedicelled. Calyxes very minute: in the males yelloviſh green; in the females reddiſh. Native of Domingo, in the mountain coppices [z].

5. Leaves at each joint five, ovate-lanceolate, bluntiſh, petioled. Racemes from the middle of the internodes, but not from the axils.—Native of America [a].

6. Stem round, aſh-coloured, ſmooth, branched. Leaves from the axils ſeveral, petioled, quinate, ſmooth. Leaflets umbelled, petioled, ovate, emarginate with a point, entire, from half an inch to an inch in length. Common petioles filiform, ſmooth, two inches long and more; partial ones a quarter of an inch long. Flowers from the ſame bud with the leaves, petioled, umbelled. Peduncles filiform, the length of the petioles. Pedicels capillary, half an inch long. It differs from R. pentaphylla in having quinate, petioled and petioluled leaves, and umbelled, axillary flowers—from R. hexaphylla, in having emarginate leaves and umbelled flowers.—Native of Japan.

7. Stem round, ſtriated, ſmooth. Leaves alternate, ſmooth. Leaflets umbelled, petioled, entire, veined, pale underneath, two inches long. Petioles round, thickened at the baſe and top, bent, a hand in length: petiolules filiform, patulous, half an inch long. Flowers ſnow-white. It differs from R. quinata in having for the moſt part ſix leaflets, which are acute, netted-veined underneath, and larger; and the flowers in racemes ſnow-white.—Native of Japan [b].

Claſſ. 13. 7. Polyandria Polygynia.

Nat. order of *Multiſiliquæ*. Lin. *Ranunculaceæ*. Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* five-leaved: *leaflets* ovate, concave, coloured a little, deciduous.

COR. *Petals* five, blunt, ſhining, with ſmall claws.
Nectary a little cavity juſt above the claw, in each petal.

STAM. *Filaments* very many, ſhorter by half than the corolla. *Anthers* upright, oblong, blunt, twin.

PIST. *Germs* numerous, collected into a head. *Styles* none. *Stigmas* reflex, very ſmall.

[x] Linn. ſpec. [y] Gærtner. [z] Swartz. [a] Linn. ſpec. [b] Thunberg.

Digitized by Google

PER. none. *Receptacle* connecting the ſeeds by very minute peduncles.

SEEDS very many, irregular, varying in figure, naked, with a reflex point.

OBS. *The eſſence of the genus conſiſts in the nectary. The other parts of fructification are always inconſtant. Hence before the nectary was obſerved, the great confuſion in this genus. This nectary is in ſome ſpecies a naked pore; in others encompaſſed by a cylindrical border; and in others again, cloſed by an emarginate ſcale.*

In R. Ficaria *the calyx is three-leaved, and the petals more than five.* R. hederaceus *has only five ſtamens.* R. falcatus *has an enſiform tail to the ſeeds, and the calyx appendicled at the baſe.* R. ſceleratus *has an awl-ſhaped receptacle, and the fruit in a ſpike. In ſome ſpecies the ſeeds are roundiſh, in others depreſſed, ſometimes they are beſet with prickles like a hedge-hog, and ſometimes they are but few in number.*

ESSENTIAL CHARACTER.

Cal. five-leaved. *Pet.* five (to eight) with a honied pore at the claw. *Seeds* naked.

Root-leaves oblong blunt ſinuate-toothed, ſtem-leaves ſeſſile digitate gaſhed, ſeeds awned.

59. Ranunculus polyphyllus.
Willd. ſpec. 1331.
Submerged leaves oblong petioled capillaceous, floating leaves wedge-ſhaped three-lobed, emerged leaves elliptic, ſtem upright.

DESCRIPTIONS, *&c.*

1. This ſpecies of Ranunculus or Crowfoot, which is commonly called in Engliſh the *Small* or *Leſſer Spearwort*, has a perennial root, compoſed of ſimple, very long, and rather large fibres. Stem a foot, or ſometimes eighteen inches high, ſpreading a little or almoſt upright, ſomewhat decumbent at the baſe, branched, leafy, round or flattened a little, ſmooth and even, frequently tinged with purple: the branches ſhort,

Digitized by Google

R A N

ſhort, alternate, divaricating. Leaves alternate, lanceolate, acute, nerved, ſmooth, perfectly entire, or elſe toothed more or leſs; the teeth blunt, unequal, callous, of a browniſh colour: the lower leaves are ovate-lanceolate, and on longer foot-ſtalks; which are channelled, and widen at the baſe: the uppermoſt and thoſe next the flowers are linear. Flowers terminating, ſolitary, on round peduncles, upright. Calycine leaflets bent back, blunt, ſlightly villoſe, yellowiſh. Petals thrice as long as the calyx, roundiſh and ſlightly obcordate, ſpreading, ſlightly concave, of a golden yellow colour, gloſſy on the upper ſide. Nectareous cavity very ſmall. Stamens numerous, to thirty. Seeds ſmooth and even [a].

Mr. Lightfoot remarks, that in ſome ſtates it differs very little from *R. Lingua*; that it varies wonderfully in magnitude, and in gravelly ſoils degenerates to a trailing dwarfiſh ſize, with linear leaves.

It grows plentifully in marſhy places, eſpecially in the wet and boggy parts of heaths and commons, where it flowers from june to ſeptember [b].

This ſpecies is very acrid. Applied externally it inflames and bliſters the ſkin. Its acrimony riſes in diſtillation. Some years ago a man travelled in ſeveral parts of England adminiſtering vomits, which like white vitriol, operated the inſtant they were ſwallowed. The diſtilled water of this plant was his medicine; and from the experience I have had of it, ſays Dr. Withering, I feel myſelf authoriſed to aſſert, that in the caſe of poiſon being ſwallowed, or other circumſtances occurring in which it is deſirable to make a patient vomit inſtantaneouſly, it is preferable to any other medicine yet known, and does not excite thoſe painful contractions in the upper part of the ſtomach which the white vitriol ſometimes does; thereby defeating the intention for which it was given [c].

It is uſed in many parts of the highlands of Scotland to raiſe bliſters: for this purpoſe the leaves are well bruiſed in a mortar, and applied in one or more limpet ſhells to the part where the bliſters are to be raiſed. This is the practice in the iſle of Skye, and other places upon the coaſt [d].

Small Spearwort varies with ſerrated leaves; with broader leaves like Plantain, hairy at the edge, ſent from Ireland to Plukenet by Gideon Bonavert [e]; and of a ſmaller ſize, with a rooting ſtem.

The laſt variety is regarded by Linneus and others as a diſtinct ſpecies. He allows it to be very nearly allied to the common Spearwort, but diſtinguiſhes it by its linear leaves, and its filiform, longer, creeping runners. In his Flora Lapponica, he deſcribes the ſtem as quite ſimple, the length of a finger or a ſpan at moſt, procumbent, and lying cloſe to the ground, having ſeveral joints, and at every joint throwing out a ſlender fibrous root; one little flower commonly terminates the ſtem; ſometimes, but ſeldom, there are two. There are two, three or four upright, ſeſſile leaves at each joint; and not unfrequently a ſingle flower iſſues from each axil [f]. Theſe differences may poſſibly be owing to its ſituation on the borders of alpine lakes. Scopoli relates that he has ſpecimens which gradually connect the common *Flammula* with the creeping variety; that a boggy ſoil promotes the growth of the plant, but the root being weak, cannot ſupport it ſo as to enable it to grow erect; hence it is decumbent, and puts forth fibres from the joints: but if the ground be harder, ſandy or dry, the root has faſter hold, and ſupports the plant in a more erect poſture.—Willdenow inſiſts that it is not a variety.

It is found in Sweden, Ruſſia, Switzerland and Germany, on the banks of lakes.

2. Great Spearwort has the habit of the preceding, but is three times the ſize. The ſtem is upright, and (from two or three to) four feet in height. The leaves are on ſhorter petioles, acuminate or more ſharply pointed, not bluntiſh, as in that. The calyx is hairy; and the hairs of almoſt all the herb are ſhort and preſſed cloſe to the leaves and ſtem, as Linneus obſerves; but this is the caſe alſo in *R. Flammula*. The flowers are large, and of a bright golden colour. Like the preceding it varies with ſerrate leaves [g].

Linneus deſcribes the ſtem as branched, leafy, often a foot and half high; the leaves as ſomewhat toothed, rugged with ſhort hairs preſſed cloſe; the peduncles oppoſite to the leaves and one-flowered [h].

The herb is acrid, like moſt of its tribe. Linneus gives it the trivial name of *Lingua*, becauſe Dalechampius gueſſed it to be the *Lingua* of Pliny. It grows generally in muddy ditches, (bogs, or by the ſides of lakes;) flowering in july. The root is perennial, like the preceding [i].

In England it is reckoned among the rarer plants, but it occurs in many places, as near London between Rotherhithe and Deptford; on Iver heath near Uxbridge; in ſeveral parts of Norfolk; on Teverſham moor near Cambridge, and in the iſle of Ely; Goldington and Oakley in Bedfordſhire; in ditches near a pool of water called Brayford, in Lincolnſhire; on the banks of the Cherwell near King's Mill, in Oxfordſhire: bogs on Malvern Chace, Worceſterſhire; Kineſon pool near Stafford; ſides of Ancott pool, Salop; in ſeveral parts of the North of England. In Scotland, as in Duddingſton Loch near Edinburgh, and about Reſtennet in Angus-ſhire.

3. This is found about Paris, and in marſhy places in the iſland of Sicily. In habit it is not unlike *Limoſella aquatica.*]

4. Root perennial. Leaves long and narrow, like thoſe of Graſs, ſeſſile. Stems little more than a foot high, dividing at the top into three or four ſlender foot-ſtalks, which are terminated by ſingle yellow flowers, like thoſe of the common Butterflower.

[Root bulbous, tuberous, cylindrical, fibroſe at the top, putting out the fibres all round like rays. Stem upright, round, ſmooth, few-flowered, with not many leaves on it. Leaves quite entire, glaucous. Calyx very ſmooth, ſpreading but not bent back [k]. Corolla pale yellow, ſomewhat ſmaller than that of *R. Lingua* [l].

It is diſtinguiſhed from *R. pyrenæus* by its yellow flowers and tuberous root: in that, the flowers are white, and the root bulbous [m].

Native of the South of France, and of Spain; on dry alpine paſtures: flowering in april and may. Specimens, ſays Dr. Withering, were brought from North Wales, by Mr. Pritchard.

Parkinſon figures it with double flowers, but deſcribes it with ſemi-double ones only.] Mr. Miller affirms that a variety with double flowers is in the Paris garden, but that we have not yet got it in England. [Probably it has fallen a victim, as Mr. Curtis expreſſes it, to the rage for novelty.—That with ſingle flowers was cultivated by Gerarde in 1596 [n].

5. Stem ſcarcely half a ſpan in height, quite ſimple, round, upright, ſoftly hairy from the middle to the top; having a ſingle ſeſſile, lanceolate-linear, ſtriated, perfectly entire leaf about the middle of it, and one flower at the top; ſometimes, but ſeldom, a ſingle peduncle bearing one flower comes out from the axil of the leaf; at the baſe the ſtem ſwells into an ovate-oblong, ſolid, white bulb, covered with oblong, imbricate, brown ſcales, which ſeem to be the remains of the root-leaves; four or more round, whitiſh, thickiſh fibres ſpring from the baſe of the bulb, and ſpread out horizontally; in their common centre binding up a ſmaller bulb, of a ſpheroidal form and blackiſh colour, netted with fibres. Root-leaves few, upright, higher than the middle of the ſtem, reſembling thoſe of *P. lanceolata*, but more acute, naked, bright green with darker lines, quite entire, running along the petiole. Flower large in proportion to the ſize of the plant: calycine leaflets ovate-lanceolate, white at the edges, pubeſcent at the back, at firſt green, then yellowiſh white; petals large, obovate-rounded, ſnow-white, entire; ſtyle ſhort, hooked outwards, ſtigma ſimple [o].

Root a ſort of bulb, covered with a tomentoſe net, and having fibres in bundles. Stem upright, filiform,

[a] Curtis, Smith. [b] Curtis. [c] Withering. [d] Lightfoot. [e] Ray, ſyn. [f] Linn. lapp. & ſuec. [g] Smith. [h] Mantiſſa. [i] Engl. bot. [k] Smith. [l] Withering. [m] Linn. [n] Hort. kew. [o] Jacquin.

Digitized by Google

even, a finger's length, with one or two leaves. Both root-leaves and ſtem-leaves linear, undivided, quite entire, even, upright, an inch long. Flowers terminating, one or two, peduncled, ſmall, white. Fruit roundiſh. Stamens roundiſh, mucronate [p].

The root is bulbed with a tuft of fibres; the lower fibres are full of tranſverſe wrinkles, like thoſe of white Hellebore. The ſtem has commonly only two flowers; but ſometimes it has ſeven or eight, and then it is a foot high or more, inſtead of three or four inches, which is its common height. Petals white, a little plaited, which gives them the appearance of being toothed and even gnawn on the edge: the nectary is in form of a tongue, or half pointed horn. The fruit often becomes oblong [q].

Haller, who deſcribes it well, remarks that it has ſometimes a double flower, and that it varies with lacerated leaves. Villars obſerves, that this plant is hardly diſtinguiſhable for the ſame ſpecies, when it deſcends from the Alps into the more fertile paſtures of the mountains.

Native of the Alps and Pyrenees, Switzerland, Carinthia, Dauphiné, Provence, Piedmont.

6. The radical bud produces two lanceolate, membranaceous leaves, ſtanding above the ground. Leaves ovate, blunt, coriaceous, pubeſcent above, when young rolled in at the baſe on long petioles. Stem quite ſimple, leafleſs. Involucre terminating, two-leaved. Peduncles from two to four, one-flowered, pubeſcent. Calyx purpliſh. Corolla whitiſh, or purpliſh, with purple nerves [r].

Root a bundle of fibres, producing at firſt two, three or four leafy ſcales, whitiſh or tinged with purple, ſcarioſe, ovate-oblong, acute and permanent. Root-leaves from two to five, cordate-ovate, quite entire, acute, fleſhy, almoſt an inch long, tomentoſe hoary, ſometimes purpliſh, marked with ſeven nerves like thoſe of Plantain, in ſhape reſembling thoſe of *Parnaſſia*. Petioles two inches long, thick, involved at the baſe in wide membranaceous nerved ſheaths. The leaves are not unfrequently ſpotted, as in *Erythronium*, *Pulmonaria*, &c. Stem ſtriated, a hand high, branched, hoary at the branches, leafy, bearing from one to twelve flowers. Leaves at the diviſion of the ſtem and branches ſolitary, ſeſſile, nerved, half embracing, more acute than the root-leaves. Peduncles axillary, ſolitary, one-flowered.

It varies with a ſtem ſcarcely two inches high, with only one, two or three flowers at moſt; in ſuch a dwarf plant the leaves and peduncles are ſo near one another as to appear to be oppoſite: hence Linneus, who made his deſcription from a dwarf ſpecimen, has attributed to it an involucre and a leafleſs ſtem. Gouan had ſpecimens of that kind from Haller; and refers Haller's *Ran. n.* 1179. to this ſpecies, which he himſelf refers to Linneus's *amplexicaulis* [s].

Native of the South of Europe. Introduced by Meſſrs. Kennedy and Lee in 1769 [t]. Mr. Curtis received it from Switzerland in the autumn of 1796; it flowered early in the ſummer of 1797; and he has given a beautiful figure of it.

7. The leaves in part ſurround the ſtalk at their baſe, whence the trivial name; in colour they differ from moſt others of the genus, being of a grayer or more glaucous hue; which joined to the delicate whiteneſs of the flowers, renders this ſpecies very deſirable in a collection of hardy herbaceous plants, more eſpecially as it occupies little ſpace, and has no tendency to injure the growth of others.

It is a native of the Apennine and Pyrenean mountains, and flowers in april and may.

Cluſius is the firſt author who deſcribes and figures this ſpecies. Johnſon, in his edition of Gerarde, copies his figure, and mentions it as being then (1633) made a denizen in our gardens [u].

8. Roots numerous, fleſhy, thickiſh, round, attenuated at bottom, in bundles, putting out fibrils. Leaves three, four, five or ſix, lying on the ground in a ring, blunt, villoſe, with unequal ſerratures, blunt or acute, on very ſhort petioles. Scape hirſute, upright. Calyx villoſe, with ovate blunt leaflets. Corolla yellow, the ſize of *R. bulboſus*. Petals five or more. Head of ſeeds roundiſh [x].

Native of Portugal, the iſland of Candia, and Barbary, where it flowers in winter.

9. This common plant, called in Engliſh *Pilewort*, and *Leſſer Celandine*, is eaſily diſtinguiſhed by its roots, formed of many knobs or tubers, ſhaped like the fig, whence its name *Ficaria*; from the top of theſe ariſe many ſmall fibres. The whole plant is ſmooth. Stems numerous, four inches or more in length, tender, leafy, red at bottom. Leaves roundiſh-heart-ſhaped, ſhining, on long foot-ſtalks, ſometimes ſpotted with white, the veins of the upper ſide preſſed in: they vary much in ſhape, and are more or leſs notched or ſcalloped about the edge: thoſe on the ſtem are ſometimes triangular, or elſe deeply three-lobed or five-lobed. Peduncles grooved, one-flowered, bent back when the flower falls. Flowers upright. Calycine leaflets three, (ſometimes four or five) concave, deciduous, with a ſmall reflex ſcale under each. Petals uſually eight, (ſeven to twelve) elliptic-lanceolate, (but varying in form,) of a golden yellow colour and ſhining, each having a ſmall ſcale at the baſe, as in the other ſpecies. Seeds ſubovate, commonly abortive.

Pilewort differs from the Crowfoots in the number of petals in the corolla, and leaflets in the calyx, hence Dillenius, Haller and Hudſon have made a diſtinct genus of it, adopting Brunfelſius's name of *Ficaria*; yet ſince it agrees with the Crowfoots in the ſame general nature and habit, as well as in the nectary or little ſcale at the baſe of the petals, it ſeems to be of the ſame natural genus with them. In the ſpring almoſt every grove, thicket and hedge-bottom is enamelled with the gloſſy golden flowers of the Pilewort: when they have been expoſed a few days to a bright ſun, the petals become white, and then ſoon fall off. It is alſo common in meadows, orchards and plantations: flowering in february, and continuing through march and a great part of april.

At its firſt appearance in the ſpring, this plant is ſmall and extends but little; but in the month of may, particularly by the ſide of moiſt ditches, it grows much more luxuriantly; and in this ſtate, as Mr. Ray has remarked, it puts forth ſmall bulbs, like grains of wheat, from the boſoms of the leaves: theſe, as the ſtalks lie on the ground, get into the earth, and become the tuberous roots of young plants. Thus the plant readily propagates itſelf; and this proviſion is the more neceſſary, becauſe the ſeeds uſually prove abortive. The roots, like thoſe of the Orchis, are renewed every year.

As Pilewort blows earlier than the other Crowfoots, it is liable to have its parts of fructification injured by the inclemency of the weather, to ſecure it from which, it has the power of cloſing its petals in a much greater degree, and in this ſtate we uſually find it from five in the evening to nine in the morning; and in wet weather.

According to Linneus, the young leaves are eaten in the ſpring by the common people in ſome parts of Sweden, boiled as greens. Though milder than moſt of the genus, this however retains ſomething of that acrimony, which many of the ſpecies poſſeſs in a high degree. The particular form of the roots probably recommended this plant as a cure for the piles; and this fancied quality was the origin of the Engliſh name. The roots are ſometimes waſhed bare by the rains, and in this ſtate have induced the ignorant, under the reign of ſuperſtition, to fancy that it rained Wheat, which theſe tubercles a little reſemble.

Linneus remarks, that Pilewort choaks other plants which grow near it. Not being eaten by cattle, and occupying much room in ſome meadows, it ought to be extirpated. Nothing diſcourages its increaſe more than coal or wood aſhes, which are both at the ſame time excellent dreſſes for meadows. It is ſometimes

Digitized by Google

ſeen in gardens with a double flower[f]. Rea ſays he found it wild, and ſet it in his garden, and that moſt of the plants in England come from this root.

10. Root fibrous, with thicker fibres among the more ſlender ones. Leaves radical, numerous, thick, concave, entire at the ſides, but with two or three teeth at the end, in the latter caſe, which is moſt frequent, the middle tooth is the largeſt; the older leaves are generally entire and blunt; they are nerved, very large, two inches long and an inch and half wide, very ſmooth, aſcending, petioled. Petiole channelled, pubeſcent, thick, flattened at the baſe, membranaceous at the edge, twice or thrice as long as the leaf, procumbent, aſcending at the end. Each plant has one, two or more runners, emerging within the petiole of a leaf, from two to four feet in length, round, ſpotted with red towards the top, pubeſcent, ſtraight, the internodes a ſpan long, rooting at the joints; and at each of theſe is one leafy ligule or ſtipule, of a linear-lanceolate form, ſheathing, inflexed. Flowering-ſtems one or more, a hand and half in length, procumbent, aſcending at the top, ſimple or ſometimees divided into two peduncles, of different lengths, almoſt naked, round, even or obſcurely ſtreaked, ſpotted with red, having one or two leafy lanceolate or linear ligules or ſtipules. Flowers ſolitary, terminating, large, reſembling thoſe of *Ran. lanuginoſus*. Calyx yellow. Petals five or ſix to ten, yellow, ſpreading very much, and even recurved, longer than the calyx, ovate-oblong. Seeds oblong, forming a globular body. It propagates itſelf by runners like the Strawberry.—Native of Siberia, beyond Baikal, in the ſalts[z].

11. Root round, browniſh, from one to two inches long, perpendicular, the thickneſs of a ſtraw, and permanent, in its whole length putting forth many fuſiform, long, pale, ſubimbricate fibres. The whole plant ſhining. Stem round, from a hand to a foot in length, upright, purpliſh next the ground. Root-leaves ſubreniform, coriaceous, firm, veined, crenate on the ſides, not cut in the ſame manner at top, but often retuſe; in the flowering plant theſe are often ſolitary, always very few, when any, for ſometimes there are none. Such a leaf, only much larger, and on a much ſhorter petiole, if not ſeſſile, occupies the upper part of the ſtem: from the axil of this comes out a one-flowered branchlet; whilſt the ſtem itſelf is terminated by a ſimilar one, or in ſtronger plants is divided into a few more; otherwiſe the ſtalks end in a ſingle flower, without any branch. The leaves of the branchlets are lanceolate, acute, quite entire and ſeſſile; in plants that are more branched, the loweſt leaves, whether bifid or trifid, have the lobes like thoſe of the uppermoſt leaves in form. Petals ſometimes ſix, yellow with the claw paler, ſpreading. Calyx ſhorter. Seeds few, ſmooth, brown, flattiſh on one ſide, roundiſh without, ending in an unarmed reflexed point[a].

Native of the Alps of Switzerland and Auſtria; the Pyrenees, Dauphiné, Piedmont, Sileſia. It appears from Salmon's Herbal (616) that it was cultivated here in 1710[b]. It flowers in may and june.]

12. This has an Aſphodel root. The lower leaves are large, and a little hairy, about three inches long and four broad, deeply crenate, divided uſually into five lobes, and on hairy footſtalks. Stems nine or ten inches high, having two or three leaves on them, cut into three ſegments and entire; dividing at top into ſeveral peduncles, each ſuſtaining one large, pale yellow flower. It flowers the beginning of june.

Native of the iſland of Candia or Crete. [Cultivated by Mr. Miller in 1759.

13. This reſembles the *ſceleratus*. Stem larger. Flowers large, yellow, deſtitute ſometimes either of calyx or corolla[c].

Native of Germany and Siberia.—According to Willdenow, it much reſembles the *auriſomus*, but the ſtem-leaves are lanceolate and toothed, not linear and quite entire.

14. Root fibrous, perennial. Stems a foot high, upright, dividing into two or three branches, leafy, round, often ſlightly downy on the upper part, ſmooth and purpliſh at bottom. Leaves generally inclined to be downy: root-leaves on long foot-ſtalks, moſtly three-cleft, deeply notched; ſometimes five-cleft; ſtem-leaves ſeſſile, divided to the baſe into many linear lobes, which are ſeldom ſubdivided or cut. Flowers terminating erect, ſolitary, of a bright golden hue; on round, pubeſcent peduncles. Calyx pale yellow, hairy, ſcarcely at all reflexed. Nectary a naked pore, not cloſed by any ſcale. In cold backward ſeaſons, in gardens, in unſheltered ſituations, and in more northern countries, the real petals are ſometimes wanting, the calyx being dilated and more coloured than uſual, ſo as to ſupply their place. It has been called *Goldilocks*, and *Sweet Wood Crowfoot*: the epithet *ſweet* being intended to expreſs, that it has none of the acrid or cauſtic flavour uſual in this genus[d]: the other epithet is expreſſive of its place of growth. It flowers in april and may.

This ſpecies is eaſily diſtinguiſhed from the other wild Crowfoots, by its yellow, patulous calyx; the nakedneſs of its nectary, which is a ſmall oblique hole running downwards at the baſe of each petal; by the bottom leaves being leſs cut, and the upper ones narrower than in moſt of the others; by the petals being frequently wanting; and by its place of growth[e]. It affects chiefly a clayey ſoil. This ſpecies has ſometimes double flowers.

15. Native of Virginia and Canada, in marſhes. Root-leaves petioled; ſtem-leaves few, ſeſſile. Flowers yellow, ſmall.

16. Root annual, compoſed of many whitiſh fibres. Herb various in ſize and luxuriance, of a pale ſhining green colour, juicy and very ſmooth, except the flower-ſtalks and upper part of the ſtem, which are occaſionally hairy. Stem ſtraight, round, hollow, thick, branched, leafy. Lower leaves on long foot-ſtalks, lobed and cut, but leſs deeply than the upper ones, which are divided to the very baſe and ſeſſile; their ſegments linear and entire. Flowers numerous, peduncled, ſmall, of a paliſh yellow. Calyx deflexed, ſhaggy. Honey-pore ſomewhat tubular. Fruit ovate-oblong, compoſed of a multitude of ſmall ſeeds[f].

This ſpecies is eaſily diſtinguiſhed, by its broad ſhining bottom leaves, thick ſtalk, ſmall yellow flowers, and ſmooth oblong ſeed-heads[g].

It is very common in watery places, where it may be found in flower and ſeed, from june to the end of auguſt.

This is one of the moſt virulent of our native plants. Bruiſed and applied to the ſkin it ſoon raiſes a bliſter, and makes a ſore by no means eaſy to heal. Strolling beggars have been ſaid to uſe it for that purpoſe, in order to excite compaſſion[h]. When chewed, it inflames the tongue; and when taken into the ſtomach, it produces violent effects. It is ſuſpected to have proved poiſonous to ſheep[i].

17. This is a very handſome ſpecies, three or four feet high and branched. Stem hollow within. Leaves large, digitate, three-lobed divided to the baſe: ſegments lanceolate, ſerrate all round, ſomewhat hirſute eſpecially at the baſe. Flower white, terminating each branch. Petals roundly ſerrate. Calyx fugacious, purpliſh[k].—Native of the Alps of Europe.]

The double-flowering variety has been obtained by ſeeds, and is preſerved in many curious gardens for the beauty of its flowers. It is by ſome gardeners called *Fair Maid of France*. The root is perennial, and compoſed of many ſtrong fibres: the leaves are divided into five lanceolate lobes; the four ſide-lobes are upon foot-ſtalks coming from the ſide of the principal ſtalk, and the middle one terminates it; they are deeply ſerrate, and have ſeveral longitudinal veins. The ſtalks riſe a foot and half high, and branch out at the top into three or four diviſions, at each of which there is one leaf, of the ſame ſhape with the lower,

but ſmaller. The flowers are pure white, and very double, each ſtanding upon a ſhort foot-ſtalk. It flowers in may. [Gerarde in 1597 ſays, "it groweth "in the gardens of Herbariſts, and lovers of ſtrange "plants, whereof we have good plentie, for it groweth "not wild any where." Gerarde was not aware that it is a variety of what he had figured under the name of *Ran. alpinus albus*.

18. This has the ſtature of *R. aconitifolius*, and it has alſo white flowers; the leaves however are not compound, but palmate, leſs thick, and more cut: the flowers are larger. In the preceding the lobes of the leaves are acuminate, and the ſegments of the upper floral leaves lanceolate.

Native of the mountains of Germany and Italy, and of the Pyrenees [l]. Introduced in 1769, by Meſſrs. Kennedy and Lee.

19. Root tuberous. Stem a foot high, round, upright, divided at top into a few one-flowered pedunCles. Root-leaves in younger plants quite entire, the reſt petioled and ternate; the upper ones binate and ſubſeſſile, or even ſimple; in other individuals they are often more irregularly compound. Leaflets lanceolate-linear, long, acute, entire. Stem, peduncles and leaves covered with a ſoft hoary down. Calycine leaflets green on the inſide with a white edge, on the outſide woolly-white, wholly turned back. Petals large, a third longer than the calyx, on the upper ſurface ſhining and deep yellow, with a greeniſh claw; on the lower ſurface greeniſh; they are flat and ſpread very much, and ſometimes are ſix in number. Head of germs ovate-oblong, yellowiſh green, with villoſe ſtigmas. Seeds ſmooth and acute [m].

Native of the South of Europe, on dry hilly paſtures. Cultivated in 1596, by Gerarde. It flowers in may and june [n].

20. Stem round, with ſpreading hairs, branched. Leaves ſlightly marked with lines. Leaflets trifid, acute, cut and ſerrate. Peduncles round, even, wandering. Calycine leaflets ovate, concave. Petals yellow, ſcarcely as big as the calyx. Stamens ſmall, the length of the corolla. Head of germs ovate, longer than the corolla. Seeds ovate, compreſſed, mucronate. It is an annual or biennial plant, native of Canada and Pennſylvania [o]. Introduced in 1789, by Chevalier Thunberg.

21. Found by Thunberg in the iſland of Nipon in Japan, flowering in may [p].

22. Stem upright, branched, pubeſcent, round, as are alſo the peduncles. Lower leaves ſimple, lobed, gaſhed, acute, pubeſcent underneath, as are alſo the petioles: upper leaves three-parted and biternate. Calyx not reflex [q]. Thunberg remarks, that all the parts are hairy, except the corolla.

Root compoſed of many thick fleſhy fangs or fibres, uniting at top into a head; from theſe are ſent forth many ſlender long fibres, ſtriking deep in the ground. From the top ariſe ſeveral leaves, compoſed of three, ſix or nine lobes of irregular forms, and cut at top into various ſegments. Between theſe ariſe the flower-ſtalks, about a foot high, taper, hairy, and branching out at a little diſtance from the root. Stem-leaves dividing into three parts, theſe again cut, and generally terminated by trifid points: the petioles are embracing at the baſe. The leaves are all hairy; the lower ones much larger and more compound than the upper. Flowers terminating, with the ſtem naked for a conſiderable length below them. They vary much in ſize and colour, and the petals are frequently of different colours on the two ſurfaces. They appear in may, and in moderate ſeaſons, or where they are ſhaded from the ſun in the heat of the day, there will be a ſucceſſion at leaſt during a month. The ſeeds ripen in july [r].

Native of the Levant. Cultivated by Gerarde in 1596 [s].]

Mr. Miller ſays it was originally brought from Perſia; but ſince it has been in Europe, many new varieties have been obtained from ſeeds, particularly of ſemidouble flowers. Theſe are ſo large, and of ſo many beautiful colours, as to exceed moſt other flowers of their ſeaſon, and even to vie with the Carnation itſelf: they are many of them finely ſcented; and the roots, when ſtrong, generally produce from twenty to thirty flowers in ſucceſſion; which qualities have rendered the Garden Ranunculus, in its improved ſtate, much admired.

Mr. Miller has made a diſtinct ſpecies of the bloody-flowered Ranunculus, under the name of *R. ſanguineus*. This, ſays he, has been almoſt baniſhed from our gardens, ſince ſo many fine varieties have been obtained from ſeeds of the Perſian Ranunculus. This has a grumous root like that: the leaves are divided by threes, twice again divided by threes, and obtuſe; the ſtalk riſes about nine inches high, and is terminated by one large double red flower. It appears at the end of april; and ſometimes one or two very ſmall flowers branch out from the ſide.

[Parkinſon enumerates the following varieties of the Garden Ranunculus or Crowfoot, as he calls it.

1. The broad-leafed Candy Crowfoot.
2. The white Candy Crowfoot.
3. The Argentine, or cloth-of ſilver Crowfoot.
4. The ſingle red Crowfoot of Aſia or Tripoli.
5. The large ſingle red Crowfoot of Aſia.
6. The red ſtript ſingle Crowfoot of Aſia.
7. The yellow ſtript Crowfoot of Aſia.
8. The double red Crowfoot of Aſia.

Ray (hiſt. 594.) beſides ſeveral which he enumerates as ſpecies, has twenty varieties, from the catalogue of the Royal garden at Paris, of the year 1665.

Rea has—

The double white, or Crowfoot of Candy.
Cloth of ſilver of Candy.
Double yellow of Aſia.
Double red of Aſia,

And thirteen others, with barbarous names.

Ranunculus of Aſia with ſingle flowers; of which eleven varieties are ſet down.

But the varieties produced of late years from the ſeeds of ſemidouble flowers are unbounded: and Mr. Maddock remarks that they are more numerous than of any other flower. Accordingly his catalogue boaſts nearly eight hundred, all with their proper names; ranged under the heads of,

1. Dark and dark purple. 2. Light purple and Gray, &c. 3. Crimſon, &c. 4. Reds, &c. 5. Roſy, &c. 6. Orange, &c. 7. Yellow and yellow ſpotted, &c. 8. White and white ſpotted, &c. 9. Olive, &c. 10. Purple and Coffee ſtriped, &c. 11. Red and yellow ſtriped. 12. Red and white ſtriped.]

23. This has a tuberous root; the leaves are decompounded and ſmooth; the ſtalks riſe near a foot high, and have one leaf of the ſame ſhape with the lower, but ſmaller; the ſtalk is terminated by one double flower, about the ſize of the common Butter-flower, of a fine bright yellow colour.

[The ſtem is commonly one-flowered and one-leafed; it occurs however very frequently with a three-flowered ſtem. It comes from Siberia with a branched ſtem. Corolla white, often eight or ten-petalled [t].

Native of the mountains of Auſtria, Dauphiné, Switzerland, Piedmont, &c. It flowers in may, and was cultivated in 1759, by Mr. Miller [u].

24. Root big and fleſhy, in form of a bulb, and very acrid, puſhing forth many long thick fibres. Hence ſprings the ſtem, gradually becoming ſmaller. Leaves alternate, dividing into three petioles, each of which divides a ſecond and even a third time, and finiſhing in flat, ſmooth, fleſhy, lanceolate leaflets; the lateral ones ſmaller and frequently once more divided. Stem from three to ſix inches high, terminating in two or more branches, often nine and even fifteen, each having a ſingle leaf at their baſe, and one handſome flower at the end: calycine leaflets blunt, covered with ruſſet or very minute hairs: petals ſel-

dom white, but almoſt always tinged with a pleaſant vinous or purple red, from five to ſeven or more in number, large, and permanent. Fruit large, oval, compoſed of from forty to one hundred ſeeds, ſmaller than in the other ſpecies[a].

Native of Lapland, Denmark, Switzerland, Dauphiné and Piedmont, on high granite mountains near the ſnow. It flowers in june, and was introduced in 1775 by Drs. Pitcairn and Fothergill[y].

Willdenow remarks, that the figure of the leaves in the Flora lapponica and Flora danica is not very good, ſo that at firſt ſight it appears to be a different plant, but the dried ſpecimens have leaves of the ſame ſhape with thoſe in the more ſouthern countries of Europe.

25. The whole plant is very ſmooth, and therefore it cannot be that which is found in the more ſouthern parts of Europe; for that is hirſute[a]. This differs from the *lapponicus* in having the calyx hirſute, the ſtem-leaves ſeſſile, the ſtem firmer, and the flower larger[a].—Native of Lapland and Norway.

26. The leaves reſemble the floating leaves of *Ran. aquatilis*. Calyx reflex, ſmooth. Petals white, two-lobed[b].

It is only two or three inches high. The numerous fibres of the root are often longer than the whole plant, they are very acrid, and inſinuate themſelves into the clefts of rocks: the leaves are ſmooth; thoſe on the ſtem are rather ſimple bractes: the calyx and petals are white; the latter blunt and even emarginate. It is often found of a larger ſize[c].

Native of Switzerland, Auſtria, Carniola, Dauphiné, Piedmont, &c.

27. Root fibrous. Root-leaf ſingle, on a filiform petiole the length of a finger, three-parted almoſt to the baſe, where the lobes are narrower, towards the top they widen, are blunt, and have three or four notches. Stem-leaf alſo ſingle, on a ſhorter petiole, ſmaller, of the ſame ſhape with the other, ſometimes in the middle of the ſtem, ſometimes near the root. In the Flora Suecica it is ſaid, that the leaves are nearly kidney-form, but three-parted to the very baſe; the middle lobe leſs and obſcurely three-lobed, the ſide lobes divided into ſeveral ſmaller ones.—Stems filiform, a ſpan high, quite ſimple and ſtraight. Flower one, terminating, yellow. Calyx yellow, commonly three-leaved, even, the ſize of the petals, turned back. Petals ſmall, ſharp at both ends. Stamens twelve to fifteen. Piſtils ſix to eighteen. Seeds acuminate, turned back at the top, forming a globe.—Native of Lapland[d].

28. Root thick and creeping, ſometimes half a foot in length, with fibres on every ſide inſinuating themſelves into the clefts of rocks. Leaves rounded, very villoſe, divided into three lobes, which are very large and cloſe to each other. The ſtem bears only one or two flowers, which are yellow and vary in ſize; it is quite villoſe and almoſt lanuginoſe, as well as the calyx, and is ſix or eight inches in height. It differs little from the *auricomus*, and perhaps may be no more than a variety, but if it be, it deſerves to be known[e]. Native of the South of France and of Barbary.

29. Root a ſolid white roundiſh bulb, flattened a little both at top and bottom, ſomewhat reſembling a ſmall Turnep: it throws out ſeveral long fibres from the under ſide, but ſcarcely appears to produce any offsets: the bulb is formed above the bulb of laſt year, and when the plant flowers, the old bulb, in a dry ſoil, may be found in a ſtate of decay under the new one, and ſurrounded by the fibres, but without the leaſt appearance of ſuckers proceeding from either of them. Mr. Woodward remarks, that in a turf containing ſix plants, the roots were all diſtinct, excepting one, which appeared from its ſize to be a ſeedling, with the old bulbs at the bottom. Stems upright, a foot high, branched above, but never producing runners below, leafy, round, hairy, many-flowered. Root-leaves on long hairy footſtalks, dilated and embracing the ſtem at bottom, ternate, trifid, variouſly cut, more or leſs hairy: ſtem-leaves ſeſſile or nearly ſo, deeply divided into numerous and narrower linear ſegments. The ſtem and each branch terminates in a ſingle flower, on a grooved, angular, hairy peduncle. Calyx-leaves ovate, concave, hairy, thin at their baſe, turned back to the peduncle ſoon after they expand. Petals bright yellow, as if varniſhed, roundiſh, emarginate, concave. Nectary covered with a ſhort inverſely-heart-ſhaped or emarginate ſcale. Germs ſmall, compreſſed, forming a little head. It propagates itſelf copiouſly by ſeed, but is of ſlow growth and long duration. The flowers are ſometimes double, but not ſo frequently as *R. acris*. It is diſtinguiſhed from the *repens*, with which it has been confounded by ſome authors, by its roots, by its never throwing out runners, and by its reflexed calyx; this laſt character ariſes from its particular ſtructure, the lower half being thin and almoſt tranſparent, and therefore not having a ſufficient degree of ſolidity to ſupport itſelf upright. Ray adds, that the upper leaves are cut into finer and longer ſegments, that the heads of ſeeds are more produced, that the ſeeds themſelves have no ſpinule at top, and that the flowers appear a little earlier. It is the ſecond flower which, next to the Dandelion, covers the meadows with dazzling yellow. Like moſt of the Crowfoots it poſſeſſes the property of inflaming and bliſtering the ſkin; particularly the root, which is ſaid to raiſe bliſters with leſs pain and more ſafety than Spaniſh flies; hence theſe roots have been applied for that purpoſe, particularly to the joints in caſes of the gout. According to Hoffman, beggars make uſe of them to bliſter their ſkins, with a view of exciting compaſſion. The juice of the herb is ſaid to be more acrid than that of *R. ſceleratus*, and if applied to the noſtrils it provokes ſneezing. The roots on being kept, loſe their ſtimulating quality, and are even eatable when boiled. Hogs are fond of them, and frequently dig them up. The herb is too acrid to be eaten unmixed by cattle, accordingly the flowering-ſtalks are left to perfect the ſeed in paſtures, ſome of it however is conſumed, and it is not improbable that this and other pungent plants, mixed with the graſſes, may act as a powerful ſtimulus, to ſome animals, as ſalt does to others. It abounds in dry paſtures, and flowers in may[f]. Beſides the name of round-rooted or bulbous Crowfoot, it is called by the common people Butter-flower, Butter-cups, King-cups, Gold-cups; and it is the Cuckow-buds of yellow hue in Shakſpeare. We muſt remark however that the *repens*, *hirſutus* and *acris* are all confounded with this, under one name by the vulgar.

30. Root fibrous, annual. Stem upright, a foot and half high, leafy, generally more branched and ſpreading, producing a greater number of flowers, and covered with ſtiffer and longer hairs than in the *bulboſus*; the hairs in that are more numerous and ſoft, but in this they are hiſpid and ſtand out very much. Foot-ſtalks of the lower leaves hollow, and if cut aſunder the nerves appear projecting into the inſide of the tube: the leaves themſelves are more perfectly trilobate than in the *bulboſus*; the middle and outermoſt lobe rounder, and leſs deeply divided at the edges; from the inner edge of each of the two ſide lobes it ſeems as if a bit were cut away: theſe leaves are frequently of a white or pale colour, in irregular ſpots, not unlike what we ſometimes meet with in the *R. Ficaria*; and the upper ſurface is full of little projecting points, whence the hairs iſſue. The upper leaves are more finely cut, and the ſegments generally linear. The calyx is reflexed, as in *bulboſus*; hence many botaniſts, not finding any other Britiſh ſpecies recorded by Linneus, with this character, concluded it to be a variety of that, though Ray and John Bauhin long ſince conſidered them as diſtinct. But although the calyx be turned back, yet before the opening of the flower it is eſſentially different, being much more pointed, as if it had been ſqueezed to a point with the fingers; and the outſide of it is very viſibly covered with little papillæ or

projecting

[a] Villars. [b] Lin. ſyſt. [c] Villars. [d] Retzius. [e] Villars. [f] Hort. kew. [g] Linn. [h] Linn. lapp. [i] Curtis, Smith.

Digitized by Google

projecting points, whence the hairs proceed. The flowers and ſeed are ſmaller than in *bulboſus*. The *hirſutus* flowers later, namely from june to october, and flouriſhes chiefly by the ſides of roads, in gardens, and among rubbiſh [g].

Obſerved by Mr. Curtis in various places near London, by the road ſide between Croydon and Mitcham, near Graveſend, and plentifully by the ſea ſide; alſo on the gravelly banks about Southampton. Mr. Ray remarked it in ſalt marſhes near Graveſend, and in moiſt clayey places where water had ſtood during the winter: Mr. Relhan, by road ſides, among rubbiſh, &c. in Cambridgeſhire: Mr. Woodward, among corn, in a clayey ſoil, and on new made banks of ſalt marſhes, by Yarmouth: Dr. Sibthorp, on South Leigh common in Oxfordſhire. Mr. Abbot ſays it is abundant in paſtures in Bedfordſhire; and there is no doubt of its being common enough, but having been taken for the *bulboſus*, it has frequently paſſed unobſerved.

31. Root perennial, conſiſting of numerous whitiſh fibres. Stems generally ſeveral from one root, a foot or more in length, beſet with rough hairs, throwing out long creeping runners. Leaves ternate, trifid and gaſhed, generally hairy on both ſides, but ſometimes ſmooth and ſhining, frequently marked with white (black, *Engl. bot.*) ſpots; on long hairy petioles dilated at the baſe: the leaflets alſo are on petioles, and are ſometimes divided only into two ſegments: the leaves are broader, darker, and more diſtinctly divided twice than thoſe of *bulboſus*: the uppermoſt leaves are quite entire. Flowering-ſtems erect, branched and leafy, generally ſupporting two flowers. Peduncles pubeſcent, commonly five-furrowed. Calyx-leaves hirſute, ſpreading, yellowiſh, membranous at the edge, deciduous. Petals of a deeper yellow than in *R. acris*, commonly emarginate or obcordate, ſhining very much on the inſide. Nectary covered with an obcordate ſcale. Stamens upwards of thirty (in *bulboſus* as many as ſixty or even eighty). Germs numerous, in a little flattened, upright head. Seeds flat, ſmooth, with a ſmall point.

This ſpecies is ſufficiently diſtinct from the other common Crowfoots (*bulboſus*, *hirſutus* and *acris*) in its creeping ſtems ſending forth roots at every joint; it is on this account more miſchievous than thoſe, as alſo becauſe it will thrive in almoſt any ſoil, and is very apt to become the principal plant of the paſturage, to the great detriment of the farmer.

From the great variety of ſoil and ſituation in which the Creeping Crowfoot is found, it aſſumes many varieties: by a river's ſide or in marſhes it will grow three or four feet high, with a ſtem nearly as large as the human thumb; in barren gravelly fields it is entirely procumbent, with a ſtem not larger than a ſmall wheat ſtraw; but in all ſtates it retains the character of the creeping ſtem, and it does not loſe it in cultivation. Its principal time of flowering is in june, but it may be found in bloſſom during moſt of the enſuing ſummer months, in meadows and paſtures, under hedges, in ſhady waſte places, church-yards and gardens.

The qualities of this and *bulboſus* are ſimilar: both bliſter the ſkin, and are very acrid in taſte.

Like the *acris* and *bulboſus* it is ſometimes found double, but more rarely [h].

32. Stem partly creeping, about two feet long, often naked and branched, terminated by ſeveral branches, which finiſh each in a peduncle a little grooved, ſuſtaining a middle-ſized yellow flower. Leaves a little villoſe, frequently with black marks in the diſk, and pale ones below the diviſions, divided into three lobes, the two lateral ones forming four others that are ſmaller, the middle one ſubpetioled; each lobe is ſubdivided into deep linear lobules. Petals blunt, ſhifting all over within, like thoſe of the *repens*; but larger. The roots, leaves, ſtems and flowers much reſemble thoſe of the *repens*, but the ſize of the leaves and their tiſſue are more like the *acris*, as alſo the hooked, yellowiſh permanent piſtils, which are only leſs recurved than in that. It has no ſenſible acrimony [i].

Native of Germany, Switzerland, Sweden, Dauphiné and Piedmont, in woods; flowering in may and june. Perennial.

33. Root perennial, tuberous, with many long ſimple white fibres. Stem upright, about two feet high, round, hollow, having cloſe-preſſed hairs on it, not very leafy, much branched at top. Leaves three-parted and five-parted, many-cleft; the ſegments black or deep purple at the points: the root-leaves on long upright petioles: ſtem-leaves nearly ſeſſile, leſs and more finely cut: the uppermoſt linear and ſeſſile: ſheaths of the foot-ſtalks hairy. Peduncles round, not grooved, hairy. Calyx hairy, ſpreading but not reflexed, yellowiſh. Petals of a ſhining yellow, ſubcordate, notched or entire. Nectary covered with an emarginate ſcale. Seeds roundiſh, flat, bending back at top, of a brown colour.

The ſcale of the nectary at once diſtinguiſhes this ſpecies from *R. auricomus*; the ſpreading calyx, from *bulboſus* and *hirſutus*; the round even flower-ſtalks, from both thoſe and *repens*; whilſt the ſmooth ſeeds prevent our miſtaking it for any ſpecies which has them rough or muricated [k]. It is known at firſt ſight from all our other wild ſpecies, by its tall, ſlim, genteel, upright growth; which circumſtance has given occaſion to the Engliſh name.

Moſt of the Crowfoots are acrid, and in ſome degree poiſonous; but this is ſuppoſed to poſſeſs the property in a conſiderable degree, whence Linneus gave it the name of *acris*. Mr. Curtis ſays that even pulling up the plant, and carrying it to ſome little diſtance, has produced a conſiderable inflammation in the palm of the hand: that cattle in general will not eat it, yet that ſometimes, when they are turned hungry into a new field of graſs, or have but a ſmall ſpot to range in, they will feed on it, and hence their mouths have become ſore and bliſtered. According to Linneus, ſheep and goats eat it; but kine, horſes and ſwine refuſe it. When made into hay it loſes its acrid quality; but then it ſeems to be too ſtalky and hard, to afford much nouriſhment: if it be of any uſe, it muſt be to correct, by its warmth, the inſipidity of the graſſes [l]. In many paſtures the flowering ſtems are left ſtanding in vaſt abundance, to diſſeminate their ſeeds: before they do that, they might eaſily be cut down with the ſcythe, or pulled up by women and children after a ſhower, which would more effectually deſtroy the plants; they ſhould be gathered into heaps and burnt. It flowers in june and july; and is confounded vulgarly with the *repens* and *bulboſus* under the name of *Butterflower* or *Butter-cups*; under a notion that the yellow colour of butter is owing to theſe plants. It is the richneſs and exuberance of the paſture that communicates this colour; and not theſe flowers, which the cattle ſeldom or ever touch.

It is frequent in gardens with a double flower, among other herbaceous perennials, under the name of *Yellow Batchelor's Buttons*.

34. Root compoſed of many long round fibres. Stem a foot or eighteen inches high, upright, rough-haired, very ſeldom branched. Leaves like thoſe of Aconite or *R. acris*, but more cut, with a pale ſpot at the ſinuſes, where they are thicker to the touch. Peduncles long, round. Seeds acute, compreſſed [l].

According to Scopoli, it is very hirſute, branched, the calyx-leaves are coloured at the edge, and the ſtyles are reflexed; it is eaſily known by its ſtature, hairineſs, and place of growth in woods and ſhade. It differs from the *acris* in this circumſtance, in flowering earlier, in being very hirſute, large, with ſcattered flowers on fiſtular peduncles.

Villars ſays that the root is creeping and tubercled; the ſtem ſoft and fiſtular, three or four feet high, a little villoſe, ſtraight and branched; the leaves large, villoſe, divided into three great lobes, irregularly cut into five or ſeven ſharp and not deep ſubdiviſions. Peduncles from ſeven to ten, not grooved; ſtraight, villoſe, cylindrical. Petals large, yellow, blunt, ſhining within.

Digitized by Google

within. Piſtils terminating in a yellowiſh hook, bent outwards and permanent. It has the calyx villoſe, and membranous at the edge, in common with the *acris* and *polyanthemos*; it is leſs acrid than the former, but a little more than the latter; and is perhaps the connecting link between the *ſaxatilis* and the *acris*, as the *polyanthemos* is between this and the *repens*, from which Haller is not inclined to ſeparate it. The nectary is truncate, and ſwollen at the baſe.

Native of Denmark, Germany, Switzerland, Auſtria, the South of France, and Piedmont. Cultivated in 1683, by Mr. James Sutherland [m].

35. This ſpecies reſembles rather an umbellate plant or an *Anemone*, than a *Ranunculus*, in its decompound, linear, villoſe, leaves; it forms conſiderable tufts, and increaſes by off-ſets. The flower is yellow, the plant is acrid, and the root is perennial [n].—Native of France and Italy.

36. Roots tuberous, oblong, in bundles, narrowing downwards and ending in a fibre. Root-leaves many, multifariouſly decompound, on villoſe petioles; with the extreme leaflets unequal, numerous, ſmooth, ſmall, linear, acute. Stem ſimple or ſeldom divided, round, upright, hirſute, half a foot high, commonly one-flowered; putting forth one, two or three leaves above the middle. Calyx-leaves coloured, ovate-oblong or lanceolate, hairy, ſharpiſh. Corolla yellow, the ſame ſize as in *R. Lingua* (or *R. illyricus*, Vahl.) Petals obovate, rounded at the top. Germs in an oblong head, reflexed at the top. It is allied to *R. chærophyllus*, but has the leaves more finely divided, the pinnules much ſmaller and more acute, the corolla twice or three times as large, and the calyx erect, not reflexed.

Native of the kingdom of Tunis, where it flowers in winter [o].

37. Root ſmall, annual, with long ſimple fibres. Stem upright, ſcarcely a ſpan high, ſometimes branched, leafy, few-flowered, hirſute with from upright ſpreading hairs. Lower leaves petioled, three-parted, cut, hairy on both ſides; upper leaves trifid or undivided. Stipules membranaceous, hairy, faſtened to the petioles. Flowers terminating, ſolitary, upright, ſmaller than in the *acris* and our other common ſpecies. Calyx reflexed, hairy, ſcarioſe at the edge. Petals rounded, gold coloured and ſhining above, underneath paler and opaque. Nectary covered with a wedge-ſhaped, retuſe ſcale. Seeds lens-ſhaped, compreſſed, margined, dotted, muricated on both ſides with irregular ſharp tubercles.

Native of the South of France, Italy and Ruſſia. Diſcovered by Mr. T. W. Dyer, in a low meadow, on the banks of the Avon, below Briſtol Hot-wells, plentifully; flowering in july and auguſt [p].

38. Root annual, compoſed of ſimple fibres. Stem upright, a foot or more in height, leafy, round, ſmooth except towards the top, where it is pubeſcent, very much branched, the branches nodding ſomewhat before flowering. Leaves the firſt pair linear, the ſecond ovate and ſerrate, the third trifid and three-toothed, the fourth twice-trifid, on longer petioles: ſtem-leaves alternate, except ſome of the upper ones, uſually three-parted, with the leaflets again deeply divided into two or three parts; theſe leaflets are linear or lanceolate-linear, and ſlightly hairy, ſomewhat narrowed at the baſe, and pointed at the end. Each flower is oppoſite to a leaf, on a long round peduncle, ſmall and brimſtone or lemon-coloured. Calyx ſpreading, hairy, yellowiſh, except at the baſe, which is whitiſh, deciduous. Petals obovate. Stamens fourteen to ſixteen. Seeds five or ſix (ſometimes eight or nine), remarkably armed on the ſides with ſtrong prominent ſpines, larger towards the margin, and projecting much more than thoſe of *R. parviflorus*, though ſometimes like them terminating in a minute hook.

Every part of the plant has a pale appearance, and is eaſily diſtinguiſhed from our wild meadow Crowfoots by this circumſtance, by its large prickly ſeeds, its annual root, and its place of growth, which is in corn fields, where it is very common among crops of all kinds, in moſt parts of Europe, but more abundantly in ſome ſoils than in others; flowering in may and june, and ripening its ſeeds before harveſt, ſo that it fills the ground, but not being a very luxuriant plant, is not a very formidable weed. Linneus affirms that the ſeeds do not come up till the ſecond year. In ſome counties it has the name of *Hungerweed*, perhaps from its indicating a ſterile ſoil. It is ſaid to be as highly acrimonious, when freſh, as any of the ſpecies. M. Brugnon, in the fourth volume of the Memoirs of the Turin Academy, relates its poiſonous effects on ſheep, who nevertheleſs eat it greedily, as do kine and horſes. It occaſions cholic, gangrene of the ſtomach, and death in a few hours. Three ounces of the juice killed a dog in four minutes. M. Brugnon thinks vinegar the beſt antidote. Happily this plant generally grows with us where it is not acceſſible to cattle; which probably is the reaſon why we have not heard of any miſchief done by it in this country; but the huſbandman would do well to guard againſt it in fallow fields, and paſtures in the neighbourhood of corn land [q].

39. Root-leaves three-lobed, ſmooth, toothed: teeth blunt, unequal. Peduncles one-flowered. Calyx reflexed, with acute leaflets. Corolla ſmall, yellow. Seed compreſſed, excavated on both ſides, oblong, acuminate, muricated here and there. Annual [r].

Gærtner, who does not diſtinguiſh this from the preceding, ſays that the fruit conſiſts of ſeveral coriaceous capſules, not diſtinct from the ſeeds themſelves; and that the ſeeds are ſometimes as many as twelve, of an ovate-lanceolate form, beaked, compreſſed, ſurrounded by a callous, hard, whitiſh, ſmooth rim, echinated on both ſides, in the middle of the ſubferruginous diſk, with ſhort little prickles, ſpreading horizontally; they are faſtened by a very ſhort obſcure chord, which enters the baſe of the capſule.

Native of the South of Europe and of Barbary, in ditches and marſhes. Cultivated in 1683 by Mr. James Sutherland.

40. Root annual, fibrous, throwing out many proſtrate ſpreading branched ſtems, which are round, hollow, leafy, and clothed like the leaves with long, ſpreading, ſoft hairs. Leaves on very long foot-ſtalks, kidney-ſhaped, gaſh-crenate; the upper ones three-lobed; the uppermoſt lanceolate and quite entire; all of them extremely ſoft to the touch. Peduncles ſolitary, oppoſite to a leaf, each bearing a ſmall yellow flower, the petals of which are ſo minute and fugacious, that they can rarely be ſeen in their proper form and number. Calyx ſpreading. Stamens few. This ſpecies is characterized very clearly by its compreſſed ſeeds, the ſides of which are muricated with thick-ſet tubercles, each ending in a minute hooked point. It flowers in may and june, and the ſeeds ripen in june and july [s].

Native of the South of Europe and of Algiers, in dry gravelly ſoils, but with us not very frequent, or at leaſt not very frequently obſerved, which may be owing to its humble growth, the ſmallneſs of its flowers, and its want of elegance in form or colour. It occurs in ſeveral places about London, as near Camberwell, about Lee Bridge, near Walthamſtow, where it was gathered by Mr. B. M. Forſter. On Green-ſtreet green, not far from Dartford in Kent. Found near Worceſter by Dr. Stokes: on Malvern hill, by Mr. Ballard. Near Norwich by Mr. Pitchford. Near Madingley, Trumpington, Shelford, Toſt and Gamlingay in Cambridgeſhire. Bullington green, Shotover hill and South Leigh in Oxfordſhire, by Dr. Sibthorp. On St. Vincent's rocks, near Briſtol, by Mr. Swayne. Near Lymington, and Lulworth Cove in Dorſetſhire, by Dr. Withering. Dr. Pulteney, in his catalogue of the more rare plants of the latter county remarks, that it is common there in corn-fields, and on fallow lands, ſome of which in the neighbourhood of Blandford, where he reſides, are overrun with it.

41, 42. Found in the Levant by Tournefort.

R A N

43. Root annual. Native of Auſtria, in corn fields, and of other parts in the South of Europe and the Levant, flowering early in ſpring, and ſoon paſſing away. Introduced in 1782, by P. M. A. Brouſſonet, M. D.

44. Roots perennial, fibrous, numerous, ſimple, whitiſh, penetrating deeply into the mud. Stems numerous, proſtrate or floating, rooting, branched, ſpreading wide, ſmooth, round, ſolid, jointed, thickiſh. Leaves kidney-ſhaped, obſcurely three-lobed or five-lobed, ſomewhat fleſhy, ſhining and veinleſs; on long flatted petioles, having a large membranous ſheath at the baſe. Peduncles not grooved, ſhorter than the petioles, and oppoſite to them, one-flowered, at firſt upright, but after the flowering is over curved back towards the ground. Flowers ſmall. Calyx-leaves membranous and yellowiſh at the edges. Petals white, oblong or lanceolate, ſomewhat blunt, larger than the calyx. Nectary a naked pore at the baſe of each petal. Stamens five to ten, but rarely more than ſeven. Seeds numerous, roundiſh, blunt, corrugated, crouded together in roundiſh heads, about the ſize of the common Tare [t].

It is nearly allied to *R. aquatilis*, and was not diſtinguiſhed from it by Linneus, Haller and Scopoli: it differs however in having three-lobed or five-lobed leaves, with the lobes rounded, not deeply cut, and entire.

Native of many parts of Europe, as Denmark, Britain, Germany, France; alſo of Barbary and Siberia; in ſlow ſhallow rivulets, eſpecially where the ſoil is ſandy, in watery places, ſhallow muddy ditches, &c. flowering from may to auguſt.

The leaves have ſometimes a dark ſpot in the middle of each, and in ſome ſituations the flowers are much larger than in others [u].

45. Root perennial, fibrous, throwing up long round ſtems, clothed with alternate leaves, having broad membranous ſtipules at the baſe of their foot-ſtalks. Leaves petioled, ſmooth; the upper floating ones ſubpeltate, three-lobed or five-lobed and cut or groſsly notched; the lower ones which grow under water three-parted multifid, ſuperdecompound, divided into fine linear or capillary acute ſegments: ſometimes all the leaves are capillary, none of them emerging from the water, and in a ſtrong ſtream their outline is much lengthened out, by the action of the current. The foot-ſtalks of the floating leaves are often very long, probably ſtretched by ſupporting the plant. Flowers on peduncles which ariſe from the ſame ſheath with the leaves and oppoſite to them, white with a yellow ſpot at the baſe. Nectary a ſhort open tube. Stamens numerous (thirty-three). Seeds corrugated [x].

Native of Europe, in ponds, ditches and ſtreams; flowering from may to july.

The flowers are ſometimes very large and make a handſome ſhow in ponds and ditches: the curious variety in the floating and immerſed leaves, adds to the beauty of this common aquatic plant. The other varieties grow in floating waters, and have all the leaves capillary. In γ they form a roundiſh outline. In δ the ſegments of the leaves are very long, parallel, and take the direction of the current. Theſe variations are clearly occaſioned by the depth and velocity of the ſtream. Dr. Sibthorp, in his Flora Oxonienſis, has made ſpecies of theſe varieties, whilſt others have united the *hederaceus* with them all, into one ſpecies.

My learned friend Dr. Pulteney (Linn. tranſ. vol. 5. p. 19.) has recorded a curious fact, with reſpect to the *R. aquatilis fluviatilis*, which contradicts the aſſertions of its deleterious qualities, and proves that it is not merely innoxious, but nutritive to cattle, and capable of being converted to uſeful purpoſes in agricultural economy.

In the neighbourhood of Ringwood, on the borders of the Avon, ſome of the cottagers ſupport their cows, and even horſes, almoſt wholly by this plant. A man collects a quantity every morning, and brings it in a boat to the edge of the water, from which the cows eat it with great avidity; inſomuch that they ſtint them, and allow only about twenty-five or thirty pounds to each cow daily. One man kept five cows and one horſe, ſo much on this plant, with the little which the heath afforded, that they had not conſumed more than half a ton of hay throughout the whole year; none being uſed, except when the river is frozen over. Hogs alſo are fed with this plant, and improve ſo well on it, that it is not neceſſary to give them any other ſuſtenance, till they are put up to fatten.

This property of Water Crowfoot is the more remarkable, as all the ſpecies have been deemed acrimonious, and ſome of them are without doubt highly ſo. It is probable that this ſpecies is rendered inert as a poiſon, by growing in the water; although it muſt be confeſſed that in other inſtances, moiſture heightens the deleterious property of vegetables, eſpecially in the umbelliferous tribe.

This remark of Dr. Pulteney's is the more important, as in the Swediſh experiments, the *R. aquatilis* is recorded as the only one rejected by all the ſpecies of domeſtic cattle. Of the common ſorts there is no doubt but that *R. Flammula*, *bulboſus*, *acris*, *ſceleratus*, and *arvenſis* are acrimonious. Before the introduction of Cantharides, they were uſed as veſicatories, and are ſaid to act with leſs pain than flies, without any effect on the urinary paſſages; but their action is related to be uncertain, and they are accuſed of frequently leaving ill-conditioned ulcers.

The acrimony, even of the moſt virulent, is wholly diſſipated in drying; ſo that in form of hay, they appear to be harmleſs. It is alſo expelled in decoction; accordingly the ſhepherds of Morlachia boil the *R. ſceleratus* and eat it: and both *R. auricomus* and *repens* are ſaid to be wholly inoffenſive, and are ranked by ſome authors among oleraceous plants.

The Ranunculi give out their acrimony wholly in diſtillation. The diſtilled water of *R. ſceleratus* is intenſely acrimonious; and when cold, depoſits cryſtals, which are ſcarcely ſoluble in any menſtruum, and are of an inflammable nature.

46. This approaches to the *parnaſſifolius*, and agrees with it in its lower leaves: but the ſtem-leaves are petioled, with the petioles dilated; the floral leaves are lanceolate; the ſtem upright; the flowers one-third only of the ſize and yellow; the root fuſiform.—Native of the mountains of Dauphiné.

47. This reſembles *R. gracilis* in the ſize and colour of the flower, but is very diſtinct in the leaves. Root-leaves many, petioled, ſcarcely half an inch in length, quite entire, truncate at the end, and having there five large blunt teeth. Stem upright, one or two-flowered. Stem-leaves two or three, alternate, remote, ſeſſile, wedge-ſhaped at the baſe, deeply five-lobed; lobes lanceolate, quite entire, ſharpiſh. Calycine leaflets elliptic, blunt, hirſute. Petals obcordate, larger than the calyx.—Native of the mountains of Siberia [y].

48. Roots fibrous, numerous. Stem ſmooth, ſtriated, near a foot high. Root-leaves crenate; lower and middle ſtem-leaves petioled, deeply three-lobed; lobes wedge-ſhaped, unequally toothed: upper ones laciniate, with narrow-lanceolate jags. Peduncles ſtriated, one-flowered. Flowers very ſmall. Corolla yellow. Seeds in a round head, ſmall, compreſſed, orbicular with a point, tubercled on both ſides. Allied to *R. parviflorus*, but differs in having the ſtem upright, and the ſtem-leaves ſmooth and deeply three-lobed.—In moiſt fields near Mayane in the north of Africa.

49. The roots conſiſt of numerous oblong bulbs in bundles. Root-leaves petioled, villoſe, orbicular, at the baſe emarginate, unequally lobed, gaſhed and crenate, the notches rounded. Stem upright, villoſe, ſlightly ſtriated, putting forth two or four-parted leaves, but ſometimes leafleſs. Peduncles few, one-flowered. Calyx five-leaved, villoſe. Corolla yellow, the ſame ſize as in *R. acris*. Petals obovate, rounded at the end.

[t] Curtis, Smith, Withering. [u] Curtis. [x] Smith, Withering. [y] Willdenow.

Digitized by Google

end. Seeds flat, margined, forming a close cylindrical spike, an inch and half in length.—Native of marshes about Algiers [a].

50. This very much resembles *R. asiaticus*, but the stem is simple, and has only one or two flowers; the primordial leaves are wedge-ovate, undivided, unequally toothed, quite entire at the base; the calycine leaflets are ovate and acute, not lanceolate; the corolla is yellow; the head of seeds elliptic, not cylindrical.—On uncultivated moist hills about Algiers [a].

51. Root-leaves rounded, uppermost cloven with the clefts lanceolate, all trifid, with the segments cut again, toothed, acute, hirsute on both sides. Petioles from an inch to a foot in length, hirsute. Stems striated, hirsute, scarcely leafy, flexuose, branching at top into peduncles.—Native of Japan [b].

52. Calyx coloured, smooth, with a few hairs at the tip only.—Native of the mountains of Dauphiné, Italy and Carniola.

53. This differs abundantly from the *nivalis*, with which it has been confounded.—Native of the mountains of Switzerland, Dauphiné, Austria, &c.

54. This approaches to the preceding, but is double the size in all its parts, and differs in having the stem-leaf toothed.—Native of the Pyrenees and Hungary.

55. This differs very much from *R. lapponicus* in the stem and leaves; nor does it at all resemble *R. salsuginosus*, with which Gunner united it.—Native of Groenland Island, Norway and Siberia.

56. Root in bundles. Root-leaves like those of *Ran. sceleratus*, three-lobed, with the lateral lobes two-lobed, and the segments bluntly three-toothed, wedge-shaped like the leaves. Stems a finger's length, two or three from one root, upright or ascending, simple. Stem-leaves wedge-form at the base, with the segments linear, bluntish, quite entire. Peduncles two, three or four, long, one-flowered, round, not grooved, very finely pubescent like the stem. Calycine leaflets coloured, smooth, blunt, spreading. Petals yellow, the size of *R. Flammula*. Head of seeds roundish. Seeds ovate, compressed, even, crowned with the blunt permanent stigma.—Native of Siberia.

57. Root hard, the thickness of a goose-quill, like that of *Doronicum*. Root-leaves roundish-cordate, very shortly three-lobed; lobes acuminate, with a few large teeth; having scattered hairs pressed close, on both sides. Stem-leaf single, petioled like the root-leaves; and in the middle of the peduncle, a small sessile lanceolate leaf, quite entire. Stem a span long, with hairs pressed close, simple or cloven above the leaf, with one-flowered peduncles. Corolla yellow, the size of *R. polyanthemus*. Head of seeds roundish. Seeds compressed, hooked.—Found by Tournefort in Cappadocia.

58. This seems to be an annual plant. Root-leaves petioled, ovate, obtuse, unequally sinuate toothed, hairy on both sides, as are the petioles. Stem upright, a foot high and more, branched, hairy. Stem-leaves sessile, digitate, with the segments of the lower ones unequally pinnatifid; of the upper ones linear and quite entire. Calyx reflex. Corolla yellow, the size of *R. bulbosus*. Heads of seeds elliptic. Seeds flatted a little, acute, subulate-awned with the awns erect.—Native of Siberia, by the river Tereck.

59. Stem long a span in height, upright, branched at top. Leaves under water very numerous, covering the whole stem, oblong, half an inch in length, on a capillary petiole an inch long: floating leaves small, half an inch long, quite entire, on a thicker petiole. Branches an inch in length and upright, spring out of the water, and bear leaves on short petioles, four or six lines long, elliptic, attenuated both ways, blunt. Flowers very small, yellow.—This is an annual plant, native of Hungary [c].]

PROPAGATION AND CULTURE.

4. 6. 7. 11. 17. 18. 19. 24. 33. 34. 39. 42. are hardy perennials, and are easily propagated by parting their roots in autumn.

The Alpine species are not so easy to cultivate in gardens. The *parnassifolius* (n. 6.) grew and flowered with Mr. Curtis in a small pot of loam and bog earth, sheltered during the winter in a frame. They require a pure air, and succeed best in a situation moderately moist and shady.

12. 23. are propagated by offsets from the roots, in the same manner as the Garden Ranunculus (n. 22.) and should be planted in a warm border, otherwise the frost will destroy the roots.

22. Persian Crowfoot or Garden Ranunculus. The Garden Ranunculus was originally brought from Persia, but since it has been in Europe, has been greatly improved by culture, and many new flowers obtained from seeds, amongst which are many with semidouble flowers, which produce seeds; and from these there are such prodigious varieties of new flowers annually obtained, which are so large, and of such variety of beautiful colours, as to exceed all other flowers of that season, and even vie with the most beautiful Carnations; these are many of them finely scented, and the roots, when strong, generally produce twenty or thirty flowers upon each; which, succeeding each other, continue in beauty a full month or longer, according to the heat of the season, or the care taken to defend them from the injuries of the weather; all which excellent qualities have rendered them so valuable, that the old sorts are almost disregarded except in some old gardens.

All the very double flowers never produce seeds, so that they are only multiplied by offsets from their roots, which they generally produce in great plenty, if planted on a good soil, and duly attended in winter.

The season for planting their roots is any time in october, for if they are planted sooner, they are apt to come up in a short time, and grow pretty rank before winter, whereby they will be in great danger of suffering by frost; and if they are planted much later, they will be in danger of perishing under ground; so that you should not keep them out of the ground any longer than the beginning or middle of october.

The beds in which the Persian Ranunculus roots are planted, should be made with fresh, light, sandy earth, at least three feet deep: the best soil for them may be composed in this manner, viz. Take a quantity of fresh earth from a rich upland pasture, about six inches deep, together with the green sward; this should be laid in a heap to rot for twelve months before it is mixed, observing to turn it very often, to sweeten it and break the clods; to this you should add a fourth part of very rotten neats dung, and a proportionable quantity of sea or drift-sand, according as the earth is lighter or stiffer; if it be light and inclined to a sand, there should be no sand added; but if it be a hazel loam, one load of sand will be sufficient for eight loads of earth; but if the earth is strong and heavy, the sand should be added in a greater proportion; this should be mixed eight months or a year before it is used, and should be often turned over, in order to unite their parts well together before it is put into the beds.

The depth which this should be laid in the beds, must be about three feet, and should be below the surface, in proportion to the dryness or moisture of the place where the beds are situated; for in dry ground it should be two feet eight inches below the surface, and the beds raised four inches above; but in a moist place they should be two feet below, and one foot above the ground; and in this case, it will be very proper to lay some rubbish and stones in the bottom of each bed, to drain off the moisture; and if upon this, at the bottom of the beds, some very rotten neats dung is laid two or three inches thick, the roots will reach this in the spring, and the flowers will be the fairer. This earth I would by no means advise to be screened very fine, only in turning it over each time, you should be careful to break the clods, and throw out all large stones, which will be sufficient; for if it is made very fine, when the great rains in winter come on, it will cause the earth to bind into one solid lump, whereby the moisture will be detained, and the roots, not being able to extend their tender fibres, will rot.

[a] Desfontaines. [b] Thunberg. [c] Willdenow.

Digitized by Google

Of this I have had many examples, but one particularly to my coſt: when I had procured a fine parcel of theſe roots from abroad, and being deſirous of having them thrive very well, I took great pains to ſcreen the earth of my beds very fine, which I had laid above two feet deep, and planted a good part of my roots therein; but the ſeaſon advancing, and having a great deal of other buſineſs upon my hands, I did not ſcreen the earth of all my beds, but planted ſome of them without doing any thing more than raking them; and the ſucceſs was, that the roots in thoſe beds which were ſcreened did, great part of them, entirely rot; and the remaining part were ſo weak, as not to produce any good flowers; whereas thoſe which were planted in the beds which were not ſcreened, did thrive and flower very well, and ſcarce any of the roots failed, though the earth of all the beds was the ſame, and were in the ſame ſituation, both with regard to wind and ſun; ſo that the damage which thoſe roots ſuſtained, was owing entirely to the fineneſs of the earth; and this I have ſeveral times ſince obſerved in other gardens.

I am aware that this depth of three feet, which I have here directed to make the beds of theſe flowers, will be objected to by many perſons, on account of the expence and trouble of preparing them, as alſo ſuppoſing it neceſſary to make the beds ſo deep, for flowers whoſe roots are ſmall; but if they will give themſelves the trouble of making the experiment, by preparing one bed in this manner, and another in the common way, and plant them both with the ſame roots, they will ſoon be convinced of their error, by the ſucceſs of the flowers. For in the beds which have been prepared of this depth, I have ſeen one root produce upards of fifty flowers, each of which grew near a foot high, and were extremely large and fair; whereas in the common method of culture, they are thought to do very well when they produce eight or ten flowers on each root, and theſe grow ſix inches high; but if a perſon will trace the length of the ſmall fibres of theſe roots, he will find them extend three or four feet downwards. And as it is by theſe diſtant fibres that the nouriſhment is taken in, for the increaſe and ſtrength of the flowers; ſo if theſe meet with a poor barren ſoil below, they ſhrink, and the flowers are ſtarved for want of proper nouriſhment in the ſpring, when it is moſt required.

The beds being thus prepared, ſhould lie a fortnight to ſettle before the roots are planted, that there may be no danger of the earth ſettling unequally after they are planted; which would prejudice the roots, by having hollow places in ſome parts of the bed, to which the water would run and lodge, and ſo rot the roots there. Then having levelled the earth, laying the ſurface a little rounding, the beds ſhould be marked out in rows by a line, at about ſix inches diſtance each way, ſo that the roots may be planted every way in ſtraight lines; open the earth with your fingers at each croſs, where the roots are to be planted, at about two inches deep, placing the roots exactly in the middle, with their crowns upright; then with the head of a rake draw the earth upon the ſurface of the bed level, whereby the top of the roots will be covered with earth near two inches, which will be ſufficient. This work ſhould be done in dry weather, becauſe the earth will then work better than if it were wet; but the ſooner after planting there happens to be rain, the better it will be for the roots; for if it ſhould prove dry weather long after, and the earth of the beds be very dry, the roots will be ſubject to mould and decay; therefore it will be proper to give a little water to the beds, if there ſhould no rain happen in a fortnight's time, which indeed is very rare at that ſeaſon of the year, ſo that they will ſeldom be in danger of ſuffering that way.

When the roots are thus planted, there will no more be required until toward the end of november, by which time they will begin to heave the ground, and the buds of their leaves appear; when you ſhould lay a little of the freſh earth, of which the beds were compoſed, about half an inch thick over the beds, which will greatly defend the crown of the root from froſt; and when you perceive the buds to break through this ſecond covering, if it ſhould prove very hard froſt, it will be very proper to arch the beds over with hoops, and cover them with mats, but eſpecially in the ſpring, when the flower-buds will begin to appear; for if they are expoſed to too much froſt, or blighting winds at that ſeaſon, their flowers ſeldom open fairly, and many times their roots are deſtroyed.

In the beginning of march the flower-ſtems will begin to riſe, at which time you ſhould carefully clear the beds from weeds, and ſtir the earth with your fingers between the roots, being very careful not to injure them; this will not only make the beds appear handſome, but alſo greatly ſtrengthen their flowers in blowing; and if the nights prove froſty, the beds ſhould be covered with mats every evening, and ſhaded from the ſun in the heat of the day. When the flowers are paſt and the leaves are withered, take up the roots, and carefully clear them from the earth; then ſpread them upon a mat to dry, in a ſhady place; after which they may be put up in bags or boxes in a dry room, until the october following, which is the ſeaſon for planting them again.

Theſe Perſian ſorts are not only propagated by offſets from the old roots, but are alſo multiplied by ſeeds, which the ſemi-double kinds produce in plenty; therefore, whoever is deſirous to have theſe in perfection, ſhould annually ſow their ſeeds, from which new varieties will be every year produced; but in order thereto, you ſhould be careful in ſaving your ſeed, or in procuring it from ſuch perſons as underſtand how to ſave it; that is, who will be careful not to leave any flowers for ſeeds, but ſuch as have five or ſix rows of petals at leaſt, and are well coloured; for ſince theſe flowers increaſe plentifully, it is not worth the trouble to ſow any indifferent ſeeds, becauſe there can be but little hopes of obtaining any good flowers from them.

Being prepared with ſeeds, about the middle of auguſt, which is the proper ſeaſon for ſowing them, you ſhould get ſome large pots, flat ſeed-pans, or boxes. Theſe ſhould be filled with light rich earth, levelling the ſurface very even; then ſow the ſeeds thereon pretty thick, and cover it about a quarter of an inch thick with the ſame light earth; after which, you ſhould remove theſe pots, pans, or boxes, into a ſhady ſituation, where they may have the morning ſun until ten of the clock; and if the ſeaſon prove dry, you muſt often refreſh them gently with water, being very careful in doing of this, not to waſh the ſeeds out of the ground. In this ſituation the pots ſhould remain until the beginning of october, by which time the plants will ſometimes begin to come up, (though often the ſeeds will remain in the earth until the end of november, before the plants appear;) but then you ſhould remove the pots into a more open expoſure, where they may have the full ſun, which at that time is neceſſary to exhale the moiſture of the earth; but toward the middle of november, when you are apprehenſive of froſt, the pots ſhould be removed under a common hot-bed frame, where they may be covered with the glaſſes in the night time, and alſo in bad weather; but in the day, when the weather is mild, they ſhould be entirely opened, otherwiſe the plants will draw up too weak. The only dangers they are in, are from violent rains and froſts; the firſt often rotting the tender plants, and the froſt will often turn them out of the ground, therefore they ſhould be carefully guarded againſt both theſe.

In the ſpring, as the ſeaſon grows warm, theſe pots ſhould be expoſed to the open air, placing them at firſt near the ſhelter of a hedge, to protect them from the cold winds; but toward the beginning or middle of april, they ſhould be removed again into a more ſhady ſituation, according to the warmth of the ſeaſon; and if it ſhould prove dry, they muſt be ſometimes refreſhed with water; but you ſhould be careful not to give it them in great quantities, which is very apt to rot theſe tender roots; and in the latter end of april or beginning of may, they ſhould be placed where they may have only the morning ſun; in which place they may

Digitized by Google

may remain till their leaves decay, when they may be taken out of the earth, and the roots dried in a ſhady place; after which they may be put up in bags, and preſerved in a dry place till the october following, when they muſt be planted in the manner before directed for the old roots.

The ſpring following theſe roots will flower, at which time you ſhould carefully mark ſuch of them as are worthy to be preſerved, and the ſingle, or bad coloured flowers may be pulled and thrown away, which is the ſureſt method of removing them from the good ſorts; for if they are permitted to remain together until their leaves decay, there may be ſome offsets of the bad ſorts mixed with the good flowers. You ſhould not ſuffer thoſe flowers, which you intend to blow fine the ſucceeding year, to bear ſeeds, if they are inclinable ſo to do, but cut off the flowers when they begin to decay; for thoſe roots which have produced ſeeds, ſeldom flower well afterwards; nor will the principal old root, which has flowered ſtrong one year, ever blow ſo fair as will the offsets, which is what ſhould be principally obſerved, when a perſon purchaſes any of theſe roots; for a great part of the complaints made by thoſe who have bought theſe roots at a dear rate, is principally owing to this. For the perſons who ſold them, being appriſed of this matter, have parted with their old roots to their purchaſers, and reſerved the offsets for their own uſe; which old roots have ſo much degenerated from what they were the preceding year, as to cauſe a ſuſpicion, whether the perſons they were purchaſed from had not changed the roots: and this degeneracy always attends theſe flowers, after having flowered extremely large and fair, or that they have been permitted to ſeed; ſo that it is abſolutely neceſſary to ſow ſeeds every year, in order to preſerve a ſucceſſion of good flowers.

The manner of preparing the beds, and the diſtance and method of planting the roots, having been already directed, I ſhall not repeat it here, but only obſerve, that theſe flowers being tender, muſt be protected from hard froſts, and cutting ſharp winds, eſpecially after Chriſtmas, when their flower-buds are forming; for if they are neglected at that ſeaſon, their flowers will rarely prove fair; nor ſhould you ſuffer them to receive too much wet in winter or ſpring, which is equally as injurious to them as froſt.

In planting theſe roots you ſhould obſerve to place the ſemi-double kinds, from which you intend to ſave ſeeds, in ſeparate beds by themſelves, and not intermix them with the double flowers, becauſe they will require to be treated in a different manner; for when the flowers of the ſemi-double kinds begin to fade, you ſhould carefully guard them from too much wet; for if they are permitted to receive hard rains, or are watered at that ſeaſon, the ſeeds rarely come to maturity, or they are ſo weak, that ſcarce one in fifty of them will grow.

When the ſeed begins to ripen (which may be eaſily known by ſeparating from the axis and falling) you ſhould look it over every day, gathering it as it ripens; for there will be a conſiderable diſtance in the ſeeds of the ſame bed coming to maturity, at leaſt a fortnight, and ſometimes three weeks or a month. When you gather the ſeed, it ſhould not be expoſed to the ſun, but ſpread to dry in a ſhady place; after which, you muſt put it up where the vermin cannot come to it, until the time of ſowing it.

By this method of ſowing ſeeds every year, you will not only increaſe your ſtock of roots, but alſo raiſe new varieties, which may be greatly mended by changing the ſeeds into freſh ground; for if a perſon continually ſows his ſeed in the ſame garden many years they will not produce near ſo fine flowers as if he procured his ſeeds at ſome diſtance, which is alſo the caſe with moſt other plants.

It will alſo be neceſſary to take away all the earth out of the beds in which the roots were blown the preceding year, and put in new, if you intend to plant Ranunculuſes there again; otherwiſe they will not thrive near ſo well, notwithſtanding you may add ſome new compoſt to the beds, and this is what all the curious floriſts continually obſerve.

[Ranunculuſes may be planted either before or after winter. In cold wet ſoils this work had better be deferred till january or february; but in dry ſoils the ſeaſon that Mr. Miller has directed is to be preferred.

After planting, in caſe of ſevere weather, it will be proper to cover the beds with ſtraw or peas-haulm to guard them againſt froſt: but this covering ſhould be always taken off whenever the weather is favourable.

In ſpring, the winter's froſts having looſened the ground, on a fine dry day, tread or beat the ground, and preſs it cloſe to the plants with the fingers, to keep out the cold parching winds. Some long ſtraw placed between the rows, will protect the plants, and keep the ground moiſt. In default of ſpring ſhowers, water muſt be applied gently between the rows.

Thoſe who are curious in theſe flowers, and value themſelves on fine varieties, and on having them flower well and long, muſt ſhade them during the ſeaſon of blooming, with hoops covered with mats, or a frame conſtructed for the purpoſe.

Such perſons as ſave the ſeed for raiſing new varieties, muſt ſuffer it to continue on the plant till it becomes brown and dry, then cut it off, and ſpread it upon paper, in a dry room, expoſed to the ſun; when quite dry, put it into a bag, and hang it up in a dry place.

In january or february, theſe ſeeds being carefully rubbed out, and cleanſed from all extraneous matter, they ſhould be ſown under a glaſs frame, ſo thick as nearly to cover the ſurface; the glaſſes ſhould then be put on, and the frame kept cloſely covered for two or three days, till the ſeed begins to ſwell, and at this time a little light earth ſhould be ſifted over it; this ſifting ſhould be repeated every week till the ſeeds are covered; but if they are covered too deep they will not vegetate.

When the ſun ſhines hot, the glaſſes muſt be raiſed to admit freſh air, and the frame muſt be ſhaded with mats.

When the ſeed-leaves appear, the young plants will require more air, and muſt be regularly but gently watered, except when there are warm ſhowers of rain.

A fine Ranunculus ſhould have a ſtrong ſtraight ſtem, from eight to twelve inches high. The flower ſhould be of a hemiſpherical form, at leaſt two inches in diameter, conſiſting of numerous petals gradually diminiſhing in ſize to the centre, lying over each other ſo as neither to be too cloſe, nor too much ſeparated, but having more of a perpendicular than horizontal direction, in order to diſplay the colours with better effect. The petals ſhould be broad, with entire well-rounded edges; their colours ſhould be dark, clear, rich or brilliant, either of one colour, or variouſly diverſified on an aſh, white, ſulphur or fire-coloured ground, or elſe regularly ſtriped, ſpotted or mottled, in an elegant manner[4].

DESCRIPTIONS, *&c.*

1. Root annual, large, fleſhy, fuſiform or ſubglobular, white within, red or white or black on the outſide. Stem upright, thick, very much branched and diffuſed, rough with pellucid briſtles. Leaves rough, lyrate. Calyx green, rough-haired. Petals pale violet, with large veins running over them[e]. Pod long, with a ſharp beak, fungous, white, with diſtant ſtreaks, many-celled: cells membranaceous, cloſed, in a double longitudinal row, along the middle ſeptum. Seeds, one in each cell, but in each row from three to twelve; ſubglobular, large, ferruginous, covered with very minute raiſed dots[f].

Native of China, Cochinchina and Japan; in all which countries it is much cultivated.—It appears from Gerarde's herbal, that it was cultivated here in 1597[g]: and it was probably in our kitchen gardens long before his time.]

From the varieties of the common Radiſh, Mr. Miller aims at making four ſorts, by his uſual argument, that from forty years experience he never found any of them to vary; and that by ſaving the ſeeds of each carefully without mixture, the produce will always prove the ſame as the plant which the ſeeds were ſaved from.

α. The firſt variety, or long-rooted Radiſh, is that which is commonly cultivated in kitchen gardens for its roots. Of this there are ſeveral ſubordinate variations: as the ſmall-topped, the deep red, the pale red or ſalmon, and the long-topped ſtriped Radiſh; which differences Mr. Miller allows to have ariſen from culture. The ſmall-topped is moſt commonly preferred by the gardeners near London, becauſe they require much leſs room than thoſe with large tops; for as forward Radiſhes are what produce the greateſt profit to the gardener, and theſe are commonly ſown upon borders near hedges, walls or pales, the large-topped Radiſh would be apt to grow moſtly at top, and not ſwell ſo much in the root as the other, eſpecially if the plants ſhould be left pretty cloſe.

β. The ſmall round-rooted Radiſh is not very common in England, but in many parts of Italy, it is the only one cultivated; the roots of this are very white, round, ſmall, and very ſweet. [It is now frequently brought to the London markets in the ſpring, generally in bunches, and is ſometimes miſtaken there for young turneps. If eaten young, it is criſp, mild and pleaſant.

γ. The large turnep-rooted or white Spaniſh Radiſh has a moderately large, ſpheroidal white root, and is eſteemed chiefly for eating in autumn and the early part of winter. Both theſe are commonly called indiſcriminately Turnep Radiſhes.

δ. Black turnep-rooted Spaniſh Radiſh has a root like the preceding, white within, but with a black ſkin; and is greatly eſteemed by many, for autumn

[e] Krocker. [f] Gærtner. [g] Hort. kew.

and

Digitized by Google

and winter eating.] Mr. Miller ſays, that the two laſt varieties are commonly cultivated for medicinal uſe, but that ſome perſons are very fond of them for the table.

[2. This has the ſtature and appearance of the common garden Radiſh, but the leaves are ſharper, and the ſtem ſhorter, diffuſed and not upright except when it is young, but ſmooth and purpliſh with a glaucous bloom. Flowers whitiſh. Pods two or three feet long, curved, one-celled, with four obſolete ſutures, two of which are gibbous at the baſe; the partition receiving the ſeeds one after another: the length of the pods prevents the ſtem from growing upright, for they lie winding on the ground, like ſerpents.

Native of Final. It is an annual plant, and was communicated by Braad in 1764[h].

3. Root annual, ſmall, ſimple, pale brown. Stem from a foot to eighteen inches in height, upright, round, branched at top, hiſpid with tranſparent hairs pointing backwards, often purple at bottom. Leaves petioled, lyrate, alternate on the ſtem, rugged: the lowermoſt having ſix or eight alternate leaflets, beſides the large one at the end; the upper one about four, the uppermoſt entire or nearly ſo; all obtuſely ſerrate or toothed; the teeth purple at the tips. Flowers peduncled. Calyx-leaves linear, upright, hiſpid with white hairs. Corolla varying much in colour, yellow, white or purpliſh, but always with dark veins: petals inverſely heart-ſhaped, entire, ſpreading, with the claws a little longer than the calyx. Pods cylindrical, compoſed of from three to ſix, grooved, one-celled joints, each containing a ſingle ſeed, ending in an enſiform, ſmooth beak. Seeds roundiſh, ferruginous, very ſmooth, of the ſame ſize with thoſe of common garden Radiſh[i].

It is obſerved by Haller and others, that each joint of the pod has at firſt two cells, but from one of the ſeeds being always abortive, and the other filling the whole ſpace, it appears to have only one cell[k]. Gærtner declares that he could never diſcern this original bilocularity of the pod; which he deſcribes thus:—it is long, acuminate, before its full maturity ſmooth, cylindrical, very obſcurely jointed; but afterwards becomes moniliform or like a necklace of beads; the joints or beads flatted like a lens, grooved, intercepted by an iſthmus, one-celled: cells bony, ſtriated, ſegregate, perforated at top and bottom for tranſmitting the receptacles, in other parts quite entire, valveleſs. Receptacle bilateral, filiform, entering the cells themſelves, and putting forth alternate umbilical chords. Seeds in each cell one, in the whole ten or twelve, turgidly lenticular, hollow-dotted, ſaffron-coloured.

It differs ſo much from *Raphanus ſativus*, not only in having a ſingle row of cells, and thoſe bony, but chiefly in the receptacles entering the cells themſelves; that Gærtner makes it a diſtinct genus.

The whole plant is commonly glaucous or of a ſea-green caſt, and every part is moſtly hairy except the pods. It differs from garden Radiſh in having narrower pods, with the articulations more diſtinct. Charlock (*Sinapis arvenſis*) is uſually one third taller than this; the ſtalks, which in that are finely grooved, hirſute, and commonly tinged of a deep red colour, are in this even, but hiſpid, and uſually glaucous. Charlock has often an unbranched ſtem, whereas this is frequently branched quite down to the bottom: the calyx is upright and cloſe in this, but in that it is ſpreading; the corolla alſo of Charlock is ſmaller, and always yellow; and when the wild Radiſh bears yellow flowers, as it moſt commonly does with us, they are of a very different yellow, namely that which is called ochroleucous; they fade almoſt to white before they decay; and whatever their colour may be, they are never without the dark purple veins.

Wild Radiſh is too abundant among ſpring corn in many places; flowering from june to auguſt; ſometimes mixed with Charlock, from which it is not vulgarly diſtinguiſhed, but more frequently abounding where the other does not occur, or is only in ſmall quantity.

Linneus, in a diſſertation in the Amœnitates Academicæ, informs us, that in wet ſeaſons this weed abounds among Barley in Sweden, and that being ground with the corn, the common people, who eat Barley bread, are afflicted with violent convulſive complaints, or an epidemic ſpaſmodic diſeaſe. Monſ. Villars, however, remarks, that this weed is ſo common in ſome of the cold moiſt vallies of Dauphiné, that it muſt needs make great ravages there, if it were as dangerous as Linneus has repreſented it, and yet this ſpaſmodic diſorder is unknown in that country: nor have I ever heard of it in England, where it abounds ſhamefully[l].

Spielmann, Beckmann, and others have written againſt Linneus on this ſubject; Krocker has proved the plant to be harmleſs by his own experiments, and even recommends it as a nutritious food for domeſtic quadrupeds, and as very agreeable to bees[m].

7. The ſea wild Radiſh has a thick white root; leaves like thoſe of the garden Radiſh; ſtems almoſt three feet high, and very much branched; pods thick, and when ripe almoſt woody, having three or four joints with one ſeed in each, reſembling thoſe of the garden Radiſh, but rather ſmaller. Mr. Stoneſtreet found it under the cliffs by the ſea-ſide, about half a mile from the fiſher-houſe at Bourn in Suſſex. It probably owes theſe differences to its ſituation.

4. This is a pygmy plant, with the habit of *Eruca*. Stems for the moſt part naked. Both root and ſtem-leaves pinnatifid, linear. Corollas large, yellow. Pods cylindrical, pedicelled, moniliform, villoſe like the ſtem, with an oblong beak. Columna's figure (*ecphr.* 2. 69.) of *Cardamine alpina inſipida*, reſembles this.—Native of Siberia[n].

5. Root biennial, ſimple, ſcarcely thicker than the ſtem. Stem a foot and half high, rugged, purpliſh at the baſe, with ſimple branches at top. Leaves petioled runcinate, even: ſegments acuminate, toothletted on the anterior margin; the terminating one narrower. Flowers in racemes. Calyx ſpreading a little or gaping, not cloſed. Petals yellow, emarginate. Stamens the length of the petals. Pod even, not jointed, fleſhy, two-valved; with a conical beak, ancipital-four-cornered. Seeds from four to ſeven on each ſide, flatted; with a white, membranaceous partition, inſinuating itſelf between the ſeeds.—Native of Italy[o].

6. This is an annual plant, native of Siberia, where it was found by Peter Simon Pallas, M. D. He ſent it to England in 1780. It flowers here in june and july[p].]

PROPAGATION AND CULTURE.

1. The ſeaſons for ſowing the ſeed of the common Radiſh are various, according to the time when they are deſigned for uſe; but the earlieſt ſeaſon is the end of october, or beginning of november, that the gardeners near London ſow them to ſupply the markets; and theſe, if they do not miſcarry, will be fit for uſe in the beginning of march following, which is full as ſoon as moſt people care to eat them. Theſe are commonly ſown on warm borders near walls, pales, or hedges, where they may be defended from the cold winds; but there are ſome who ſow Radiſh-ſeeds among other crops the middle of ſeptember, and, if theſe are not deſtroyed by froſt, they will be fit for uſe early in february; but theſe muſt be eaten while they are young, for they ſoon grow ſticky and ſtrong.

The ſecond ſowing is commonly about Chriſtmas, provided the ſeaſon be mild, and the ground in a fit condition to work; theſe are alſo ſowed near ſhelter, but not ſo near pales and hedges as the firſt ſowing. If theſe are not deſtroyed by froſt, they will be fit for uſe the beginning of april; but in order to have a ſucceſſion of theſe roots for the table through the ſeaſon, you ſhould repeat ſowing the ſeeds once a fortnight, from the middle of january till the beginning

[h] Linn. mant. [i] Curtis, Fl. ruſt. Smith. [k] Woodw. M. S. [l] Curtis, Fl. ruſt. [m] Krocker. [n] Linn. ſpec. [o] Linn. ſuppl. [p] Hort. kew.

of

of april, always obſerving to ſow the latter crops upon a moiſt ſoil and in an open ſituation, otherwiſe they will run up and grow ſticky before they are fit for uſe.

Many of the gardeners near London ſow Carrot-ſeed with their early Radiſh, ſo that when their Radiſhes are killed, which ſometimes happens, the Carrots will remain: for the ſeeds of Carrots commonly lie in the ground five or ſix weeks before they come up, and the Radiſhes ſeldom lie above a fortnight under ground at that ſeaſon; ſo that theſe are often up and killed, when the Carrot-ſeed remains ſafe in the ground; but when both crops ſucceed, the Radiſhes muſt be drawn off very young, otherwiſe the Carrots will be drawn up ſo weak, as not to be able to ſupport themſelves when the Radiſhes are gone.

It is alſo a conſtant practice with the kitchen-gardeners to mix Spinach-ſeed with their latter crops of Radiſhes. When theſe are drawn off, and the ground cleaned, the Spinach will thrive greatly, and in a fortnight's time will as completely cover the ground, as though there had been no other crop. If it be of the broad-leaved kind, this Spinach will be larger and fairer than it commonly is when ſown by itſelf; becauſe where there is no other crop, the Spinach-ſeed is commonly ſown too thick, and the plants are therefore drawn up weak; but in this management, the roots, ſtanding pretty far apart, have room to ſpread; and if the ſoil be good, the plants will attain a conſiderable ſize, before they run up to ſeed.

When the Radiſhes are come up, and have five or ſix leaves, pull them up where they are too cloſe, otherwiſe they will run to top, and the roots will not increaſe in bulk. In doing this, ſome only draw them out by hand; but the beſt method is to thin them with a ſmall hoe, which will ſtir the ground, deſtroy the young weeds, and promote the growth of the plants. For drawing ſmall, leave them at three inches diſtance; but at ſix inches, if they are to ſtand longer.

For ſaving Radiſh-ſeed, at the beginning of may prepare a ſpot of ground, proportionable to the quantity of ſeed intended to be ſaved. Dig it well and level it; then draw up ſome of the ſtraighteſt and beſt-coloured Radiſhes, and plant them in rows three feet diſtant, and two feet aſunder in the rows; obſerving, if the ſeaſon be dry, to water them until they have taken root: after which they will only require to have the weeds hoed down between them, until they are advanced ſo high as to overſpread the ground.

When the ſeed begins to ripen, guard it carefully againſt birds. When it is ripe, the pods will change brown: then it muſt be cut, and ſpread in the ſun to dry; after which it muſt be threſhed, and laid up for uſe, where no mice can come at it.

The Turnip Radiſh muſt not be ſown till the beginning of march, and the plants muſt be allowed a greater diſtance than the common ſpindle-rooted ſort. The ſeeds of this are apt to degenerate, unleſs they are ſet at a diſtance from that.

The white and black Spaniſh Radiſhes are commonly ſown about the middle of july, or a little earlier, and are fit for the table by the end of auguſt, or the beginning of ſeptember; they will continue good till froſt ſpoils them. Theſe muſt be thinned to a greater diſtance than the common ſort, for their roots grow as large as Turneps, and therefore ſhould not be left nearer than ſix inches.

To have theſe roots in winter, draw them before hard froſt comes on, and lay them in dry ſand, as is practiſed for Carrots, carefully guarding them from wet and froſt; thus they may be kept till the ſpring.

[The ground where any ſorts of Radiſh are to be ſown, ought to be well trenched up in ridges, and levelled down at ſowing down, the clods broken, and the ſurface laid even; that the roots may have full ſcope to run down.

Cos or other Lettuce may be ſown with the ſpring crop of Radiſhes, along with the Carrots. Sow the ſeeds all together broad-caſt pretty thick in the early ſowings; raking them in well with a large rake.

The London gardeners cover the early crops with ſtraw, ſuffering it to remain till the plants are fairly come up, and then raking it off lightly every mild day, but putting it on every night, at leaſt when there is any appearance of froſt. Dry fern will anſwer the ſame purpoſe; and it is better ſtill to throw mats, ſupported on wooden pegs or on hoops, over the beds, at night and on ſevere days.

If very dry weather ſhould happen in march and april, the crop muſt be watered morning and evening.

Radiſhes are ſown very thick, like Creſſes and Muſtard, to cut in the ſeed-leaf, for ſalads; both in the natural ground and on hot-beds.

From Chriſtmas to Candlemas, Radiſhes are raiſed on hot-beds for the root. Eighteen inches depth of dung is ſufficient to bring them up; and ſix or ſeven inches depth of light rich mould. Sow the ſeed moderately thick, cover it half an inch thick, and put on the lights: the plants will come up in a week or leſs; and when they appear, either lift the lights or take them off occaſionally, according to the weather: in a fortnight thin them to the diſtance of an inch and half or two inches: in ſix weeks they will be fit to draw.

If there are no frames to ſpare, the beds may be covered with mats over hoops; and the ſides ſecured by boards or ſtraw-bands. Or in want of dung, if the beds be covered with frames, and the lights be put on at night and in bad weather, the plants may be raiſed for uſe a fortnight ſooner than in the open borders.

DESCRIPTIONS, *&c.*

1. 3. Both theſe ſorts grow naturally in the warmeſt parts of America; Mr. Robert Millar ſent the ſeeds of them from Carthagena in New Spain, where he obſerved the ſhrubs growing in great plenty. Theſe riſe with ſeveral ligneous ſtalks, which grow ſeven or eight feet high, ſending out a few ſmall ſide branches, covered with a ſmooth green bark when young, but as they are older, their bark changes to a gray. The leaves are placed by fours at each joint round the branches; thoſe of the third ſort are two inches and a half long, and an inch and a half broad in the middle, a little hairy, of a light green, and have a few ſlight indentures on their edges; the leaves of the other ſort are full as long, but are a third part narrower, of a thinner ſubſtance, and much ſmoother. Theſe differences continue in the plants which are raiſed from ſeeds, for I have ſeveral times propagated them both from ſeeds, and have conſtantly found the ſeeds produce the ſame as the plants from which they were taken. The flowers are produced on ſlender foot-ſtalks, which ariſe from the wings of the leaves; they are tubulous and globular at their baſe, and are ſucceeded by roundiſh berries about the ſize of thoſe of the Privet, which turn black when they are ripe. Theſe plants flower moſt part of the ſummer, and the fruit ripens in autumn and winter; the leaves and ſtalks have a milky juice, which flows out if they are broken.

[1. This is a ſmall tree, ſhining all over very much, upright, full of a white glutinous milk, twelve feet high. Leaves at the joints of the twigs in fours, lanceolate, quite entire, ſharp, petioled; the two neareſt five inches in length, twice as long as the two others. Common peduncles racemed, terminating, half an inch long, two or three together. Flowers ſmall, without ſcent, having white petals. The fruits are at firſt yelloviſh, but at length become very dark purple, are milky, and three times as large as a Pea[q]. They are globular, fleſhy, twin, two-ſeeded. Nuts or ſtones like thoſe of Grapes, of a bony ſubſtance, whitiſh, wrinkled, ſwelling at the baſe, gibbous, drawn to a point at top, compreſſed; keeled at the back, a little convex or flat on the belly; within bay-coloured; poliſhed very ſmooth, half-two-celled, with the partition incomplete, faſtened to the belly. Seed in each ſtone one, compreſſed, attenuated to both ends, doubled, with the lower extremity bent back[r].

[q] Jacquin. [r] Gærtner.

Native of South America, of Domingo and other iſlands of the Weſt Indies. Cultivated by Mr. Miller in 1739. It flowers here from june to ſeptember[s].

2. Native of New Spain. Stem ſhrubby, branched; all the leaves ſolitary[t].

3. This is an upright ſhrub, the whole of it milky, from a foot to eight feet in height, with all the parts of a correſponding ſize, according to the ſoil and ſituation. The younger branches ſubtomentoſe. Leaves in fours, obovate, attenuated to the baſe, acute, wrinkled, tomentoſe underneath, quite entire, the two neareſt longer than the other two. Petioles hirſute, round. Common peduncles branched, terminating in fours[u]. (Cymes peduncled, ſeveral, and two at the forkings of the ſtem[x].) Flowers reddiſh, ſmall, without ſcent. Calyx five-leaved; leaflets lanceolate. Segments of the corolla ſquared, emarginate, ſcarcely oblique: hairs in the throat without order. Drupe obſoletely bifid, firſt red, then dark-coloured. Nuts wrinkled, flat on one ſide, convex on the other, two-celled. Kernels ſolitary, ſeldom more in a nut, one of the cells becoming abortive[y]. Gærtner deſcribes the fruit as an ovate-globular twin berry, with two ſtones in it, which are like thoſe of Grapes, wrinkled and two-celled.

Native of the Caribbee iſlands and the neighbouring continent. Browne informs us, that this little ſhrub is very common in the Savannas about the town of Kingſton in Jamaica, ſeldom riſing there above three or four feet from the ground; that the berries are ſmall, black and ſucculent, and the leaves very beautifully covered with a light down, which is ſcarcely perceptible to the naked eye; that the whole ſhrub is full of milk, and more or leſs of a deleterious nature.

4. This is a milky upright ſhrub, three feet high. Leaves in fours, lanceolate, acute, thickiſh, quite entire, tomentoſe on both ſides, but very much underneath; the two neareſt longer than the others. Common peduncles racemed, terminating and axillary. Flowers ſmall, ſcentleſs; leaflets of the calyx five, ovate: petals white, with ovate ſegments. Fruit the ſize of a pea, at firſt red, then black[z].

The tube of the corolla in *R. nitida* is globular-ventricoſe below the border; the border of the corolla in *R. pubeſcens* is blunt, in *R. tomentoſa* acute[a]. This is a native of Carthagena, in New Spain, on rocks, and on the walls and gates of the town[b].]

PROPAGATION AND CULTURE.

Theſe plants are propagated by ſeeds, which ſhould be ſown in autumn ſoon after they are ripe; for if they are kept out of the ground till ſpring, the plants rarely come up the ſame year; and this is frequently the caſe with thoſe ſeeds which are brought to England.

The ſeeds ſhould be ſown in pots filled with freſh earth, and plunged into a hot-bed of tanners bark; for as they are very hard, they frequently remain a long time in the ground; therefore when they are in pots, they may be ſhifted from one bed to another as their heat decays. When the plants come up, they muſt be frequently refreſhed with water, but it muſt not be given them in large quantities; for as the plants are ſucculent and full of a milky juice, they are in danger of rotting with too much moiſture. They ſhould alſo have a large ſhare of freſh air admitted to them in warm weather, and when they are about two inches high, they ſhould be tranſplanted each into a ſeparate ſmall pot filled with freſh light earth, and plunged into a hot-bed again, obſerving to ſhade them from the ſun until they have taken new root; after which time they ſhould have free air admitted to them every day, in proportion to the warmth of the ſeaſon. In this hot-bed the plants may remain till toward Michaelmas, when they ſhould be removed into the ſtove, and plunged into the tanners bark, where they muſt be kept warm, and not have too much moiſture in cold weather.

[s] Hort. kew. [t] Cavanilles. [u] Jacquin.
[x] Willdenow. [y] Jacquin. [z] Idem.
[a] Willdenow. [b] Jacquin.

Digitized by Google

As theſe plants are natives of very hot countries, they will not live in the open air in England, therefore they ſhould conſtantly remain in the ſtove; and if they are continued in the bark-bed, they will thrive much faſter than when they are placed on ſtands in a dry ſtove. But in the ſummer ſeaſon they ſhould have a large ſhare of freſh air admitted to them, and the leaves of the plants muſt be now and then waſhed with a ſponge, to clear them from the filth they are apt to contract; which, if ſuffered to remain, will retard the growth of the plants. Where due care is taken of them, they will thrive very faſt, and the ſecond year will produce flowers, and continue ſo to do for many years, and will perfect their ſeeds in England. They may alſo be propagated by cuttings, which ſhould be laid to dry for two or three days before they are planted; and then ſhould be plunged into a moderate hot-bed of tanners bark, obſerving to ſhade them until they have taken root, after which time they may be treated as the ſeedling plants.

DESCRIPTIONS, *&c.*

This genus was made up by Monſieur L'Heritier, out of the ruins of *Athanaſia*; with the addition of two or three ſpecies from *Oſmites* and *Leyſera*. All the ſpecies are natives of the Cape of Good Hope, whence they were introduced by Maſſon.

1. 2. See the deſcriptions under *Athanaſia*.

4. The leaves and flowers in this ſpecies are double the ſize that they are in the preceding ſpecies, *R. microphylla*; the ſtems are upright, not diffuſed.

5. This and the preceding ſpecies are very nearly allied in their infloreſcence and habit; but in this the leaves are as it were three-cornered, and ſomewhat fleſhy, with pedicelled glands ſcattered over them: theſe are wanting in *R. paſſerinoides*.

6. This ſpecies is annual; the preceding ſpecies are all perennial, and woody at bottom [e].

7. Root annual. Stem branched both above and below. Leaves alternate, ſubpubeſcent. Flowers terminating. Calyx ovate, ſmooth and even, yellow, Corolla yellow: diſk ſmall; ray lanceolate, the length of the calyx. Seeds oblong, with a very ſhort crown of little briſtles [f].

8. 9. See Athanaſia.

10. Very nearly allied to the preceding, and perhaps only a variety of it [g].

11. See *Leyſera paleacea*.

12. It may be doubted whether this is ſufficiently diſtinct from the preceding. The pappus is tubular and toothed at the tip in both.

13. 14. 15. Theſe three ſpecies have the calyx wider than in the reſt, with the inner ſcales larger. It is ſcarcely the ſame in *R. paleacea* [h]. For *R. calycina* ſee *Oſmites calycina*.

16. This has no pappus. It is ſufficiently foreign to this genus [i].

PROPAGATION AND CULTURE.

See ATHANASIA.

RELHANIA. See *Athanaſia, Leyſera, Oſmites.*

RENEALMIA. (*So named by the younger Linneus from Paul Reneaume, a phyſician at Blois, author of* Specimen hiſtoriæ Plantarum, Par. 1611. qu.)
Lin. gen. Schreb. n. 2. *Lin. ſuppl.* 7.

[e] L'Heritier. [f] Linn. ſuppl. ſub Zoegea. [g] L'Heritier. [h] Idem. [i] Idem.

Claſſ. 1. 1. Monandria Monogynia.
Nat. order of *Scitamineæ*. *Cannæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* ſuperior, one-leafed, tubular, breaking out at the top into two or three irregular teeth.

COR. one-petalled: *tube* ſtraight, cylindrical: *border* trifid; the two upper ſegments oblong, rounded, equal; the lower ſcarcely longer than the upper ones, channelled, oblong.

Nectary faſtened along the tube of the corolla, aſcending beneath the upper ſegments, ſtraight, the length of the corolla, oblong, one-toothed on each ſide at the baſe, then with an excavated ſinus, widening and bluntly three-lobed at the tip.

STAM. *Filament* none. *Anther* one, inſerted into the throat of the tube, in the ſinus of the lower ſegment of the corolla, oppoſite to the nectary, ſtraight, linear, emarginate, grooved on the inſide, of the ſame length and breadth with the ſegment of the corolla.

PIST. *Germ* inferior, oblong, obſcurely three-ſided, ſmooth. *Style* filiform, very ſmooth, erect, the length of the corolla. *Stigma* peltate; with a flat head; the ſide verging to the nectary, truncate, perforated with a hole running down into the ſtyle.

PER. *Berry* oblong, three-grooved, cylindrical, ſmooth, ending in a navel, fleſhy, three-celled in the middle. *Cells* ſoft, membranaceous.

SEEDS very many, oblong, truncate, four-cornered, very ſmooth.

ESSENTIAL CHARACTER.

Cal. trifid. *Nect.* oblong. *Cal.* one-leafed, burſting into two or three irregular teeth. *Anther* ſeſſile, oppoſite to the nectary. *Berry* fleſhy.

SPECIES.

1. Renealmia exaltata.
Lin. ſuppl. 79. (excl. ſyn. Rumphii) *ſyſt.* 50. *Willd.* 6.

DESCRIPTION, *&c.*

1. This is a tree twenty feet in height, with a ſtraight trunk. Leaves five or ſix feet long, lanceolate, waved about the edge. The raceme or bunch of flowers ſprings from the trunk above the root.—Native of Surinam, where the inhabitants are fond of the preſerved fruit [k].

RENEALMIA. See *Tillandſia.*]

RESEDA, (*of Pliny: à reſedando dolores; from its ſuppoſed quality of aſſuaging pain.*)
Lin. gen. n. 608. *Reich. n.* 664. *Schreb. n.* 831. *Tournef. t.* 238. *Juſſ.* 245. *Gærtn. t.* 76. Luteola. *Tournef. t.* 238. Seſamoides. *Tournef. t.* 238.
Claſſ. 11. 3. Dodecandria Trigynia.
Nat. order of *Miſcellaneæ α. Capparides*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, parted: *parts* narrow, acute, erect, permanent; two of which gape more, for the uſe of the melliferous petal.

COR. *Petals* ſome (3. 5. 6.) unequal, ſome of them always half-three-cleft; the uppermoſt gibbous at the baſe, melliferous, the length of the calyx.

Nectary a flat upright gland, produced from the receptacle, placed on the upper ſide between the ſtamens and the uppermoſt petal, converging with the baſe of the petals.

STAM. *Filaments* eleven or fifteen, ſhort. *Anthers* erect, obtuſe, the length of the corolla.

PIST. *Germ* gibbous, ending in ſome very ſhort *Styles*. *Stigmas* ſimple.

PER. *Capſule* gibbous, angular, acuminate by means of the ſtyles, gaping between them, one-celled.

SEEDS very many, kidney-form, faſtened to the angles of the capſule.

OBS. *There is ſcarcely any genus, the character of which is ſo difficult to be determined, for the ſeveral ſpecies ſport both in number and figure.*

The eſſential character conſiſts in the trifid petals, one of them melliferous at the baſe; and in the capſule not being cloſed, but always gaping.

[k] Willd. & Linn. ſuppl.

Luteola

Luteola *has a four-parted perianth; three petals; the uppermoſt melliferous and half-ſix-cleft, the ſides oppoſite and trifid; two very ſmall entire petals are frequently added below the others. Styles three. Stamens very many.*

Alba *has the perianth ſix-parted; petals ſix, almoſt equal, all half-three-cleft; ſtyles four; capſule quadrangular; ſtamens always eleven.*

The other ſpecies *have the perianth five-parted; five diſſimilar trifid petals; three ſtyles; and very many ſtamens.*

ESSENTIAL CHARACTER.

Cal. one-leafed, parted. *Petals* laciniate. *Capſ.* gaping at the mouth, one-celled.

Leaves entire and three-lobed, calyxes equalling the flowers.

DESCRIPTIONS, &c.

1. [Root annual or biennial, fuſiform, ſmall. Stem from a foot to three feet in height, upright, grooved, hollow, leafy, branched. Root-leaves ſpreading on the ground in a ring, blunt, entire, ſmooth, bright yellowiſh green, ſhining, ſeſſile, from three to five inches in length, and near half an inch in breadth, waving about the edge; they have commonly a minute reddiſh toothlet on each ſide of the baſe: ſtem-leaves alternate, linear-lanceolate; the upper ones linear. Spikes terminating, upright but bending at the top, very long, ſometimes having three hundred and fifty flowers or more; each flower ſtands ſingle on a ſhort pedicel, and has one awl-ſhaped yellowiſh bractle at the baſe; they are of a pale yellowiſh colour, about one-ſixth of an inch in diameter, and have little ſmell. Calyx four-cleft; the ſegments lanceolate, and the two upper wide aſunder. Petals three; the upper one four-cleft, the two lateral ones trifid, or

Digitized by Google

ſome entire and linear. Nectary at the baſe of the upper petal, notched. Stamens from twenty to thirty or more, hanging down. Germ wrinkled, pyramidal, three-ſided with blunt corners. Styles none, but three ſtigmas. Capſule three-valved, rolled inwards ſo as to fold about the ſeeds, which are ſmall, roundiſh, and black, in ſix rows along the angles of the capſule.

This plant is not uncommon in a wild ſtate in paſtures, fallow fields, waſte places, and on dry banks and walls. Mr. Swayne obſerves that it is one of the firſt plants which grow on the rubbiſh thrown out of coal-pits. It flowers in june and july.

The root and bottom leaves are formed from the fallen ſeeds before winter; and thus it happens in this, as in many other caſes, that the wild plant is biennial, whilſt the cultivated plant, growing from ſeeds ſown in the ſpring, is annual.

It is an obſervation of Linneus's, that the nodding ſpike of flowers follows the courſe of the ſun, even when the ſky is covered; pointing towards the eaſt in a morning, to the ſouth at noon, weſtward in the afternoon, and to the north at night.

Cattle do not eat this plant, except that ſheep ſometime crop it. Dyers make conſiderable uſe of it; for it affords a moſt beautiful yellow dye for cotton, woollen, mohair, ſilk and linen. Blue cloths are dipped in a decoction of it, in order to become green. The yellow colour of the paint called Dutch Pink is obtained from this plant. The entire plant, when it is about flowering, is pulled up for the uſe of the dyers, who employ it both freſh and dried.

In various authors it has the names of Dyer's-weed, Yellow-weed, Weld, Would, Woold and wild Woad. The London dyers know it by the name of *Woold*, and it muſt be carefully diſtinguiſhed from the true *Woad* or Iſatis tinctoria [l].

2. Root perennial. Stem a foot high, almoſt upright, with white hairs on it. Branches from the upper axils coming out later. Leaves alternate, ſeſſile, hairy along the keel, ſcarcely ciliate, quite entire without any tooth. Raceme terminating, with white flowers. Anthers eleven, yellow. Germs ſix, placed on a common ſtipe [m].]

From the root ariſe a few ſlender woody ſtalks, a foot and half high, thinly ſet with linear obtuſe leaves, of a grayiſh colour; the upper part of the ſtalk has, for a conſiderable length ſmall flowers of a whitiſh purple colour, ranged in a very looſe ſpike, ſitting cloſe. Theſe appear at the end of may, and the ſeeds ripen in auguſt. It grows naturally upon the mountains of Spain.

[Vahl doubts whether the *Reſeda caneſcens* of Linneus's Species Plantarum, be the ſame plant with that of the Syſtema Vegetabilium, edit. 14. His ſpecimen (which is probably from Forſkahl) agrees perfectly with the deſcription given in the Syſtema; but the ſpecific character given in the ſpecies, and Cluſius's figure ſeem to indicate another plant.

3. From a white longiſh root ariſes a round branching ſtalk, with very ſtiff oblong leaves reſembling thoſe of Linaria, and terminated by a long ſpike of ſmall pale yellow flowers, ſucceeded by angular bifid capſules, full of ſmall pale ſeeds [n].

Native of the South of Europe. It is a perennial plant, and flowers here from may to july. It was cultivated in 1748, by Mr. Miller [o]. Ray had a ſpecimen of it at Montpelier, from Charles Sueiker, of Dantzick [p].

4. This has the appearance of *R. Seſamoides*. Stem ſuffruticoſe, upright, branched: branches round, ſcattered, ſmooth. Leaves ſcattered, thickiſh, acute, ſmooth. Raceme terminating: flowers rather remote: calycine leaflets ſix, minute, edged with white: petals wedge-ſhaped, quite entire [q].

Native of the Cape of Good Hope. Introduced from thence by Maſſon in 1774. It flowers in auguſt, and is biennial [r].

5. Root thickiſh, white, hard, perennial. Stems three or four, a long ſpan in height, rod-like, round. Leaves ſcattered, ſmall, thick, like thoſe of Flax. Flowers many, crouded, of an herbaceous purpliſh colour. Seeds ſmall, blackiſh.—Native of the South of Europe [s].

6. Root perennial. Stems ſeveral, proſtrate, a palm and half in height, ſtriated, ſomewhat angular. Root-leaves elliptic-ſpatulate, of a long tongue-ſhape: ſtem-leaves ſeſſile, almoſt linear, but wider towards the end, obtuſe, all ſmooth, neither ſinuate nor toothed. Stems very often ſimple. Flowers in very long racemes, ſubſeſſile. Calyx very deeply five-cleft. From the calyx a receptacle ſupporting the flower. Petals white. Germs five, diſtinct, becoming one-ſeeded capſules. The calyx expands, and turns back, three of the ſegments pointing upwards, and two downwards [t].

Native of the South of France. Introduced in 1787, by Mr. Zier. It flowers in july and auguſt [u]. In the Kew catalogue it is marked as annual.

7. Root and ſtem next the ground perennial, often twice the thickneſs of the thumb and more, very ſhort; from the top of this ſpring ſeveral aſcending ſtalks, ſmooth with raiſed ſtreaks. Leaves pinnate, with five or ſeven lanceolate, decurrent pinnas, which are waved, even, and curved back at the end. Spikes ſeveral, alternate. Stamens eleven. It forms a ſort of intermediate link between *R. undata* and *alba*.—Native of Spain [x].]

8. Lower leaves large, compoſed of many narrow alternate leaflets, of a grayiſh colour. Stems two feet and a half high, with leaves like the others, but diminiſhing in ſize to the top, terminated by ſhort thick ſpikes of white flowers.

[This is a very ſmooth plant. Stems ſtriated, branched, diffuſed, arched upwards. Pinnules lanceolate, waved, quite entire, decurrent; with ſmaller ones interpoſed. Midrib white, convex underneath, ſtriated. Flowers in racemes, crouded, on very ſhort pedicels. Calyx permanent, five parted, ſmall; the ſegments linear-ſubulate, acute, unequal. Petals four or five, white, unequally laciniate, almoſt equal, longer than the ſtamens; which are about twelve in number. Styles four, very ſhort. Capſule oblong, four-cornered, wrinkled, one-celled, opening at top. Seeds brown, kidney-form [y].

It is an annual plant (Miller ſays biennial) native of the South of France, Spain and Barbary. It flowers from may to october, and was cultivated here in 1633 [z].

9. Root perennial. Stem a foot high, ſtriated and angular, ſtiff and ſtraight. Leaflets lanceolate, decurrent, acute, waved; the alternate ones ſmaller and more upright. The uppermoſt leaves have none of theſe ſmaller leaflets. Racemes terminating. Calyx five-parted. Petals five, trifid, white. Anthers ten, yellow. Three piſtils in ſome flowers, in others five. Capſules the largeſt of any in this genus.—Native of Spain [a]] and Italy.

It is a biennial plant; the lower leaves unequally pinnate, with ſome of the intermediate leaflets much leſs than the others, and of a different ſhape. The ſtalks riſe two feet and a half high, with ſmaller leaves, indented on their edges. The flowers are produced in ſlender looſe ſpikes at the top of the ſtalks; they are ſmall and white, and appear in june; the ſeeds ripen in ſeptember.

10. [Root annual, ſomewhat woody. Stems ſeveral, branching into a thick woody tuft, round, ſtriated, ſmooth, leafy. Leaves trifid or pinnatifid, the lower ones frequently bipinnatifid; the ſegments linear, channelled, ſmooth, more or leſs waved. Spikes terminating, upright, many-flowered, with a ſmall bracte to each. Flowers ochroleucous or ſulphur-coloured. Calyx ſix-cleft. Petals ſix, variouſly lobed. Nectary fringed. Stamens hanging down [b]: as many as twenty. The ſegments of the calyx are linear, and the uppermoſt is the ſmalleſt [c]. Capſule a triangular priſm,

three-celled at bottom, one-celled at top, gaping, terminated by three upright horns [d]:—oblong, ſubtrigonal, blunt at the corners, roughened, one-celled, rolled in at the edge. Seeds ſmall, brown, kidney-form, ſhining [e].

Ray and Haller obſerve that it has an oleraceous taſte, reſembling that of Cabbage.

Native of moſt parts of Europe, in corn fields and meadows; with us chiefly on a calcareous ſoil: alſo on walls. It flowers from june to the end of autumn.]

Mr. Miller makes two ſpecies of the common ſort, and the curled variety. The latter, he ſays, is our common ſort in England. The lower leaves are winged, and every lobe is cut into three ſmall parts, and curled, having ſome ſmall indentures on the edges. The ſtalks riſe about the ſame height as thoſe of the other, but are terminated by longer and looſer ſpikes of flowers, which are paler and approach to a white.

The other, which is common in the South of France, Italy and Spain, is a biennial plant, with a long white root, a little woody. Leaves unequally winged, with entire lobes. Stalks channelled, two feet high. Stem-leaves like thoſe below, but ſmaller, and terminated by long looſe ſpikes of pale yellow flowers, compoſed of ſeveral unequal petals, of which the two upper are largeſt, the ſide ones leſs, and the lower ſo ſmall as to be ſcarcely viſible; they are of a ſingular figure, and appear as if one leaf came out of two others.

[The R. criſpa gallica of Boccone, was obſerved by James Sherard, M. D. in barren cloſes about Roehill and Northfleet in Kent.

Dillenius remarks, that the ſtalks were permanent, and that there is little doubt of this being perennial and diſtinct from the other. With due deference to the opinion of this great botaniſt, I ſhould rather impute the firmneſs and permanency of the ſtalks to the dryneſs of the ſoil in which the plants grew.

Dr. Withering thinks that it merits farther attention; and adds, that it is not an uncommon plant in Portugal, and that in all the ſpecimens he ſaw there the leaves were curled, but without any other difference. All foreign authors inſiſt upon the leaves being curled.

Dr. Smith treats the *curled* Rochet as a very trifling variety, having the leaves only a little more curled, and in conſequence of a mild climate or ſeaſon, living through the winter as happens to other ſpecies of this genus.]

11. This is an annual plant, which has generally a ſingle fleſhy tap root running deep in the ground, ſending out ſeveral trailing ſtalks near a foot long, and dividing into ſmaller branches. Leaves ſmall, ſome wedge-ſhaped and entire, others cut into three obtuſe ſegments. The ends of the branches are terminated by looſe ſpikes of flowers, ſtanding upon pretty long peduncles. Calyx large, divided into ſix ſegments almoſt to the bottom; petals white.

[Stems procumbent, angular, branched. Leaves like thoſe of *R. odorata*, ſmooth, ſpatulate-lanceolate, blunt, running down into the petiole. Flowers looſely racemed, pedicelled. Calyx permanent, ſix-parted, longer than the petals, very large after flowering: ſegments unequal, blunt. Petals ſix: the four upper finely fringed, with claws at the baſe and arched; the two lower ſimple, very narrow. Styles three, very ſhort [f]. Capſule membranaceous ovate-oblong, (inflated,) three-cornered, ſubhexagonal, *Desf.*) having a ſlight groove on each ſide, one-celled, three-toothed, (three-cuſped, *D.*) at the top, pervious. Seeds about twenty-four, kidney-form and curved in, rugged with very minute wrinkles, of a cinereous bay colour or whitiſh; faſtened in a double row to each angle of the capſule, which is there a little thickened [g].

Native of the South of Europe (and Barbary, in dry ſandy ſoils.) It was cultivated in 1739, by Mr. Miller; and flowers from june to ſeptember.

Dalibard having cultivated this plant, found it after ſome generations to become like ſweet Mignionette. He then ſowed the ſeeds of this which was become ſweet by cultivation, in its natural dry ſoil, and it loſt all the ſmell, returning to its original ſtate.

12. Stem a foot high, aſcending or upright, branched at top, rugged. Lower leaves lanceolate, alternate, undivided, rugged underneath; upper ſtem-leaves trifid. Raceme terminating, long, upright. Calyx ſix-leaved, very ſhort, linear, ſpreading. Corolla ſix-petalled, white: the two upper petals three-petalled; the middle one ſmaller; the two lateral ones two-parted; the loweſt ſmaller; the two loweſt linear. Stamens pale. Germ three-cuſped, ſcarcely longer than the calyx. Styles none. Stigmas ſimple.

Native of Paleſtine [h]. Vahl remarks that the leaves are waved.]

13. The root of the Sweet Reſeda, which is commonly known by the French name, *Mignionette*, is compoſed of many ſtrong fibres, which run deep in the ground. Stems ſeveral, about a foot long, dividing into many ſmall branches. Leaves oblong, about two inches in length, and three quarters of an inch broad in the middle, of a deep green colour. The flowers are produced in looſe ſpikes at the ends of the branches, on pretty long ſtalks, and have large calyxes; the corollas are of an herbaceous white colour, and ſmell very like freſh Raſpberries.

[It reſembles *R. Phyteuma* very much, but the leaves are more waved: the calyxes are not longer than the corolla: the branches are declining, with more briſtles ſcattered over them: the flowers are of a dull colour, but have a high ambroſial ſcent; they are moſt commonly four-ſtyled: the lateral ſegments of the petals in this ſpecies, but the middle ones in *R. Phyteuma*, are ſhorter [i].]

Mr. Miller remarks, that theſe two plants are ſo much alike, as by ſome perſons to be taken for the ſame; and that ſuch as have been impoſed upon, by having ſeeds of *R. Phyteuma*, which has no ſcent, given them for thoſe of *R. odorata*, have ſuppoſed that the plant was degenerated. [See the account of Dalibard's experiment above.

Desfontaines deſcribes the ſtems as aſcending, ſtriated, branched; the leaves as lanceolate, blunt, ſimple or ſometimes two-parted or three-parted; the flowers in racemes, pedicelled; the calyx permanent, ſix-parted, the ſegments linear-awl-ſhaped. Petals commonly ſix, but ſometimes more, ſmall, white, the two upper ones clawed at the baſe, arched, covering a rounded buckler, and very finely fringed, the lateral and lower ones very narrow. Anthers ſaffron-coloured. Styles commonly three, ſhort. Capſule oblong, toruloſe, three-cuſped at top.

The luxury of the pleaſure-garden, ſays Mr. Curtis, is greatly heightened by the delightful odour which this plant diffuſes; and as it grows more readily in pots, its fragrance may be conveyed into the houſe: its perfume, though not ſo refreſhing perhaps as that of the Sweet-Briar, is not apt to offend the moſt delicate olfactories. It flowers from june to the commencement of winter.]

It is ſuppoſed to be a native of Egypt; whence the ſeeds were brought to the South of France. [Monſ. Desfontaines found it in Barbary, in the ſands near Maſcar.] The ſeeds were ſent to Mr. Miller from Leyden, by Dr. Adrian van Royen, and ſucceeded in the botanic garden at Chelſea. Soon after, they were brought from the South of France by Lord Bateman [k]. [I have been informed that the Sweet Mignionette had been cultivated at Paris from about the year 1725, and that it was brought to England from thence in 1739 or 1740. It appears from the ſixth edition of Mr. Miller's Dictionary, that he cultivated it in 1752; but he probably had it ſome years ſooner from Holland. No mention however is made of the Mignionette, in the ſecond volume of his Dictionary in 1739, in the fourth edition of 1743, or in the fifth edition of 1748.]

PROPAGATION AND CULTURE.

None of theſe plants, except the laſt, are cultivated in gardens unleſs for the ſake of variety, having very little beauty to recommend them, and not being of any known uſe; but whoever has a mind to have them, need only ſow their ſeeds in autumn, and when

[d] Krocker. [e] Desfont. [f] Ibid. [g] Gærtner. [h] Linn. mant. [i] Linn. ſpec. [k] Mill. fig.

Digitized by Google

the plants come up, if they are thinned and kept clean from weeds, it is all the culture they require; and if their ſeeds are permitted to ſcatter, the plants will come up in plenty, and ſometimes become troubleſome weeds.

The ſeeds of the laſt ſort ſhould be ſown on a moderate hot-bed in march, and when the plants are ſtrong enough to tranſplant, they ſhould be pricked out upon another moderate hot-bed to bring them forward; but they ſhould have a large ſhare of air in warm weather, otherwiſe they will draw up weak.

About the end of may the plants may be planted out, ſome into pots, to place in or near the apartments, and others into warm borders, where they may remain to flower and ſeed. For the plants which grow in the full ground, often produce more ſeeds than thoſe which are in pots; but at the time when the ſeed-veſſels begin to ſwell, the plants are frequently infeſted with green caterpillars, which, if they are not deſtroyed, will eat off all the ſeed-veſſels.

If the ſeeds of this plant are ſown on a bed of light earth in april, the plants will come up very well, and when they are not tranſplanted, will grow larger than thoſe which are raiſed in the hot-bed, but they will not flower ſo early, and in cold ſeaſons will ſcarcely ripen their ſeeds. [In a warm dry border however, the ſeeds will come up ſpontaneouſly, and grow very luxuriantly: but to have the flowers early in ſpring, the ſeeds ſhould be ſown in pots in autumn, kept in frames through the winter; or on a gentle hot-bed in ſpring.] The plants may alſo be preſerved through the winter in a green-houſe, where they will continue flowering moſt part of the year, but the ſecond year they will not be ſo vigorous as the firſt.

1. The firſt ſort is the Weld, which is accounted a rich commodity for dyeing; where this is cultivated, the ſeeds are commonly ſown with Barley in the ſpring, and after the Barley is taken off the ground, the Weld begins to make ſome progreſs, and the next ſeaſon is pulled up for uſe. This has been long practiſed, and it will be difficult to prevail on the cultivators of this plant to depart from their old cuſtoms; but if any perſons will follow the directions here given, I can from experience promiſe them much better ſucceſs.

Though the Weld will grow upon very poor ſoil, yet the crop will be in proportion to the goodneſs of the land; for upon very poor ground, the plants will not riſe more than a foot high, whereas upon good ground I have meaſured them upwards of three feet, and the ſtalks, leaves, &c. have been in proportion; ſo that the better the ſoil is upon which it is ſown, the greater will be the produce.

The beſt way to cultivate this plant, is to ſow it without any other crop; if the ground is ready by the beginning or middle of auguſt, that will be a good ſeaſon; the land ſhould be well ploughed and harrowed fine, but unleſs it is very poor, it will not require dung; when the ground is well harrowed and made fine, the ſeeds ſhould be ſown; one gallon of the ſeeds is ſufficient to ſow an acre of land, for they are ſmall. If rain falls in a little time after the ſeeds are ſown, it will bring up the plants, and in two month's time they will be ſo far advanced as to be eaſily diſtinguiſhed from the weeds; then they ſhould be hoed in the like manner as Turneps, always obſerving to do it in dry weather, for then the weeds will ſoon die after they are cut up; at this time the plants may be left about ſix inches diſtance; if this is done in dry weather, and the work well performed, the plants will be clean from weeds till the ſpring; but as young weeds will come up in march, ſo if in dry weather the ground is hoed again, it may be performed at a ſmall expenſe while the weeds are young, and then they will ſoon decay; and if after this there ſhould be many more weeds appear, it will be proper to hoe it a third time, about the beginning of may, which will preſerve the ground clean till the Weld is fit to pull. The beſt time to pull the Weld for uſe, is as ſoon as it begins to flower, though moſt people ſtay till the ſeeds are ripe, being unwilling to loſe the ſeeds; but it is much better to ſow a ſmall piece of land with this ſeed, to remain for a produce of new ſeeds, than to let the whole ſtand for ſeed; becauſe the plants which are permitted to ſtand ſo long will be much leſs worth for uſe, than the value of the ſeeds; beſides, by drawing off the crop early, the ground may be ſown with Wheat the ſame ſeaſon; for the plants may be drawn up the latter end of june, when they will be in the greateſt vigour, ſo will afford a greater quantity of the dye.

When the plants are pulled, they may be ſet up in ſmall handfuls to dry in the field, and when it is dry enough, it may be tied up in bundles and houſed dry, being careful to ſtack it looſely, that the air may paſs between to prevent its fermenting.

That which is left for ſeeds ſhould be pulled as ſoon as the ſeeds are ripe and ſet up to dry, and then beat out for uſe; for if the plants are left too long, the ſeeds will ſcatter. The uſual price of the ſeed is ten ſhillings a buſhel.

[Mr. Miller, in the directions given above, affirms, that though Weld will grow upon very poor ſoil, yet the crop will be in proportion to the goodneſs of the land. Dr. Withering, on the contrary, ſays, that it is cultivated in ſandy ſoils; a rich ſoil making the ſtalk hollow, and not ſo good for uſe. It is certain that all the Reſedas affect a dry ſoil; and probably a ſandy loam ſuits the Weld beſt in cultivation: on poor ſand the crop will be light, and heavy clays are certainly not proper for it[1].

Mr. Marſhall, in order to try whether this uſeful plant be an object of the Norfolk culture, ſowed one acre and three-eighths with two pints of Turnep ſeed and two pints and a half of Weld ſeed, on the 16th of auguſt.

The ſoil, which was a lightiſh ſandy loam, had been ploughed three times as a fallow for Wheat. He gave it a fourth ploughing, harrowed and ſowed the Turnep ſeed, harrowed again and ſowed the Weld ſeed; re-harrowed, the horſes trotting.

It was hoed at a conſiderable expenſe with ſmall Carrot hoes, yet it got full of Poppies and other weeds.

On one end of the piece, where the Turneps were a bad crop, the Weld was very good; but upon the whole, only indifferent.

Mr. Marſhall on this remarks, that the Turneps were extremely prejudicial to the Weld; that there was no ſeed from them worth turning ſheep to, until the plants began to run in the ſpring; and then, in a few days, they ſtarted up, and drew the Weld up with them, ſlender and ſickly: that had the Weld been ſown alone, and twice hoed, the crop would have been much better, and the ſoil left cleaner.

Mr. Marſhall apprehends that there is no occaſion to leave the plants ſo thick on the ground as is uſually done; but that ſix or eight inch hoes might be uſed with propriety in ſetting out the plants: and if ſo, the expenſe of hoeing would be little more than for Turneps.

From this and other experiments Mr. Marſhall is of opinion, that Weld may be raiſed with conſiderable profit in Norfolk; eſpecially in war-time, when it is dear. But he is alſo clearly of opinion, that it is not the intereſt of landlords to encourage the culture of it, without ſome rigid reſtrictions in their leaſes, to prevent tenants from carrying off ſuch a quantity of vegetable matter, without laying on a proper quantity of manure, as in the uſual covenant relative to hay and ſtraw: for it is not the corn only, but the ſtraw likewiſe, that is carried off in the ſhape of Weld; perhaps to the amount of a ton or upwards on an acre[2].

ſeveral, a foot high, round, even, not hollow, tough, quite ſimple, ſcarcely the thickneſs of a quill, having one knot. Leaves ſcarcely any. Leafy ſheaths two or three, towards the root, imbricate, even, brown, ſlightly mucronate at the tip with a leafy rudiment. The ſheath in the middle of the culm has a ſimilar leafy rudiment. Spathe terminating, unfolding into other inner ſpathes, and into compound racemes. The fructification is with difficulty extricated in the females. Anthers compreſſed, brown edged with white [t].

Thunberg (in prodr. cap.) retains this as a diſtinct genus.

9. The houſes are commonly thatched with this ſpecies at the Cape of Good Hope, both in town and country, and ſometimes whole huts are built with it. A roof thatched with it will laſt twenty or thirty years, and would laſt much longer, if the ſouth-eaſt wind did not blow much dirt into it, which cauſes it to rot [u].

DESCRIPTION, *&c.*

Fruteſcent, erect, four feet high, ſomewhat branched. Branches few, thickiſh, rigid, unequal, ſhort, hairy. Leaves by fours in whorls, crouded, lanceolate-linear, approximating, ſeſſile, blunt, upright, one-grooved above with impreſſed dots, two-grooved underneath. Flowers lateral, towards the extremities ſeſſile, crouded, upright, almoſt concealed among the leaves. Bractes lanceolate, wider below, acute, keeled, hirſute, longer than the calyx. Corollas ruſeſcent, on the outſide towards the tip hirſute. Stamens inſerted below the throat of the tube. It bears a very great affinity to the *Convolvuli*; *C. oenotheroides* eſpecially combines this plant with that genus.

Native of the Cape of Good Hope, on the higheſt mountains [t].

GENERIC CHARACTER.

CAL. none: unleſs the corolla be taken for it.

COR. *Petal* imperforate, externally rude, internally coloured, funnel-form: *tube* turbinate-cylindrical: *border* ſpreading, divided, acute.

Scalelets five, very ſmall, each at the baſe of each diviſion of the border, converging.

STAM. *Filaments* as many as there are ſegments of the corolla, awl-ſhaped, inſerted into the petal under the ſcalelet. *Anthers* ſmall.

PIST. *Germ* roundiſh. *Style* filiform, the length of the ſtamens. *Stigma* blunt, divided into fewer ſegments than the corolla.

PER. *Berry* roundiſh, naked, divided into fewer parts internally than the corolla.

SEEDS ſolitary, roundiſh, gibbous on one ſide, flatted on the other.

OBS. *That part of the flower, which is here called the corolla, is more properly the perianth; and the ſcalelets placed cloſe to the ſtamens ſhould be named the petals.* Schreb.

Frangula *has an emarginate ſtigma, a four-ſeeded berry, and a five-cleft corolla.*

Rh. catharticus *has a four-cleft ſtigma, a four-ſeeded berry, and a four-cleft corolla. It is dioecous, and four-ſtamened.*

Paliurus *has three ſtyles, a three-celled nucleus, and a five-cleft corolla, with a membranaceous rim ſurrounding the berry or drupe.*

Alaternus *has a trifid ſtigma, a three-ſeeded berry, and a five-cleft corolla. It is Polygamous Dioecous with males and hermaphrodites. The ſcalelets of the corollas are wanting.*

Zizyphus *has two ſtyles, a two-celled nucleus, and a five-cleft corolla. Drupe.*

ESSENTIAL CHARACTER.

Cal. tubular. *Cor.* ſcales defending the ſtamens inſerted into the calyx. *Berry.*

SPECIES.

Thorny.

Prickles in pairs ſtraight, leaves ovate acute toothed ſmooth—fruits oblong pedicelled.

DESCRIPTIONS, *&c.*

1. The purging or common Buckthorn riſes with a ſtrong woody ſtem to the height of twelve or fourteen feet, ſending out many irregular branches: the young ſhoots have a ſmooth grayiſh-brown bark; but the older branches have a darker and rougher bark, and are armed with a few ſhort thorns. Leaves two inches and a half long, by one and a quarter broad, dark green above but pale or light green beneath, having a pretty ſtrong midrib, and ſeveral nerves proceeding from it, which diverge towards the ſides, but meet again near the point: they ſtand upon pretty long ſlender foot-ſtalks. The flowers come out in cluſters from the ſide of the branches: thoſe of the male have as many ſtamens as there are diviſions in the petal; thoſe of the female (or hermaphrodite) have a roundiſh germ, which afterwards becomes a pulpy berry of a roundiſh form, incloſing four hard ſeeds.

[Branches rigid, alternate, round, ſmooth, with a thorn at the end. Leaves in bundles, ſmooth, the ſerratures glandular: the younger ones pubeſcent. Stipules awl-ſhaped, in pairs, the length of the petiole. Flowers from the ſame bud with the leaves, aggregate on axillary one-flowered peduncles, which are of the ſame length with the petioles: they are of a pale or yellowiſh green colour, four-cleft, and dioecous or polygamous commonly, but not always. Stigma four-cleft. Berries black, the ſize of a ſmall pea, four-celled, four-ſeeded [x].—Native of Europe, in hedges and woods: flowering from the end of april to june, and ripening its berries about the end of ſeptember.

According to Pallas, the Buckthorn is common in the champaign and temperate parts of Ruſſia and Southern Siberia, but ſcarcely beyond the Irtis. The trunk is often thicker than a man's arm, and the wood very hard, of a reddiſh colour. The flowers are for the moſt part hermaphrodite, and cluſtered; in the gardens fewer and nearly ſolitary.

The juice of the unripe berries has the colour of ſaffron, and is uſed for ſtaining maps or paper: theſe are ſold under the name of French berries. The juice of the ripe berries, mixed with alum, is the ſap-green of the painters; but if the berries be gathered late in the autumn, the juice is purple. The bark affords a beautiful yellow dye [y]. The inner bark, like that of Elder, is ſaid to be a ſtrong cathartic, and to excite vomiting. The berries operate briſkly by ſtool, but occaſion thirſt, and dryneſs of the mouth and throat, accompanied frequently with ſevere griping of the bowels, unleſs ſome diluting liquor be plentifully taken with them. The juice made into a ſyrup is the officinal preparation. About an ounce is a moderate doſe; and it was formerly much employed as a hydragogue, from this quantity to two ounces: but it is now falling into diſuſe, and is rarely preſcribed except in conjunction with other medicines of this claſs. It is ſaid that the fleſh of birds which feed upon theſe berries is purgative [z].

2. This is a procumbent ſhrub. The leaves are villoſe underneath. The calyx goblet-ſhaped and toothleſs. Stigmas two, reflexed [a].

It differs from the preceding, according to Gerard, in having the ſegments of the corolla the length of the tube, never longer.

Scopoli adds, that it differs in the whole habit, its place of growth, the naked ſpines, the leaves villoſe underneath, the calyx toothleſs and goblet-ſhaped, and the berries having commonly one cell empty [a].

The root fixes itſelf ſo firmly in the fiſſures of the rocks, that it cannot be pulled up. The ſtem divides immediately into branches that are very much ſubdivided, and form a very cloſe head. Spines both terminating and lateral, naked. Leaves elliptic, ſerrulate. Flowers abundant, axillary and below the leaves. Calyxes yellowiſh. Petals minute. Style undivided and truncate. Berry three-celled, with one cell commonly empty [b].

According to Villars, this ſpecies forms the link between R. catharticus and ſaxatilis; being lower and more branched than the former, and leſs tufted than the latter.]

Mr. Miller deſcribes it as an humble ſhrub, ſeldom riſing more than three feet high, ſending out many irregular branches, covered with a dark-brown bark. Leaves ending in acute points, three quarters of an inch long, and near the baſe half an inch broad, of a yellowiſh green and thin conſiſtence. The flowers come out upon ſmall ſpurs on the ſide of the branches, each ſtanding upon a ſeparate ſhort footſtalk; they are of a yellowiſh herbaceous colour, having a ſhort ſwelling tube, and being cut into five acute ſpreading ſegments. They appear in june, but are not ſucceeded by berries here.

Monſ. Duhamel ſays, that this fruit gathered green is the *Grain d'Avignon*, uſed in dyeing yellow; but I have been aſſured by a gentleman of ſkill, who reſided long in the South of France, that the Avignon berries were the fruit of the narrow-leaved Alaternus. I therefore gathered a quantity of the berries of this Alaternus before they were full ripe, and carried them to two eminent dealers in this commodity, who both aſſured me, after making trial of them, that they were Avignon berries, and that if I had a large quantity, they would purchaſe them all. Since then this Alaternus is one of the moſt common ſhrubs in the South of France, whence the Avignon-berries are brought, we may ſuppoſe that Monſ. Duhamel has been ill-informed. See n. 7.

[Native of the South of Europe. Cultivated in 1683, by Mr. James Sutherland [c].

3. A ſhrub of about three feet high, very much branched, the branches ſpreading and terminated by a ſpine: the bark of a brown aſh-colour and ſmooth. The leaves are ſublinear, obtuſe, narrower at the baſe, very ſmooth, ſeſſile, faſciculated; the faſcicles alternately ſcattered: ſeveral tranſparent pores are diſſeminated throughout the whole ſurface. The flowers ariſe ſolitary from the faſcicles of leaves, and are two or three, ſupported on capillary footſtalks ſhorter than the leaves. The calyx is yellow, urceolated, ſemiquadrifid, ſometimes trifid, and very rarely quinquefid, with broad ſharp ſegments, from the diviſions of which proceed ſmall laciniæ or ſcales, which are ſetaceous, of a red colour, and guard the ſtamens. There is no corolla, unleſs you call the calyx ſuch. The filaments of the ſtamens are equal in number to the ſcales, and are capillary, upright-recurvate, and ſituated within the calyx near the germ: anthers globoſe. Germ globoſe, reddiſh; ſtyles two, ſometimes three, a little recurved: ſtigmas thickened and red. Capſule top-ſhaped, black, biſulcate, ſometimes three-cornered, and opening with a two-fold or three-fold diviſion. Seeds two or three, ſubtriquetrous, pale.

RHA

It is a native of calcareous mountains in ſome parts of Spain, where it grows plentifully.

Cavanilles obſerves that in Pallas's figure of this ſpecies, the leaves are repreſented ſerrated, and the fruit globular, which he attributes to the fault of the engraver ſince it is not the caſe in ſuch plants as he has examined [d].

4. This is a ſhrub, the height of a man, upright but twiſted, ſtiff with few abrupt irregular ſpreading branches; ſometimes unarmed, with ſhort branches, ſometimes more branched with thorns at the end of both branches and branchlets. Trunk among the rocks often twiſted, covered with a thin brown ſtrigoſe bark. Wood very hard, rigid, of an orange red colour, but frequently of a deeper red. Branches ſtraight, rigid, alternate, with an aſh-coloured brown bark, ſometimes dichotomous, with thorns even from the diviſions. Branchlets leafy, unarmed, very ſhort, rugged with the ſcars of leaves, leafy at the end. Leaves very long, attenuated into a ſort of petiole, ſmoothiſh, with very fine diſtant ſerratures; in the more branching ſhrub, which has the leaves narrower, ſcarcely viſible. Peduncles frequent in bundles among the leaves. Male flowers both on a diſtinct ſhrub, and with the females, ſmall, four-cleft, with the ſegments ſharp and yellowiſh. Female flowers never on the male ſhrub, ſimilar, greeniſh; with a ſuperior germ, three ſtyles longer than the calyx, filiform, and a ſubcapitate ſtigma. Berry the ſize of a pea, globular-triconvex, ſharply umbilicate. Seeds three, large, ovate-oblong, three-ſided convex.

Perhaps it may be a variety of that next to be deſcribed, owing to climate and place, but it differs much in habit.

Native of Siberia, by the Selenga and collateral rivers of Mongolia, and in the open pine woods, in warm ſituations. The Mongols uſe the wood to make their images, on account of its hardneſs and colour. The berries yield a deep yellow dye.

β. This is a ſmall buſhy tree, very much branched, ſcarcely ever attaining a fathom in height; the bark brown and even, on the branches of a yellowiſh-teſtaceous colour and ſhining: the branches ſtiffer, more long and ſlender, and more abundant than in the preceding, becoming thorny at the tip, having frequent bundles of leaves on them. Leaves on the annual twigs in bundles; but on the branches alternate, ſeſſile, lanceolate-linear, attenuated eſpecially at bottom, ſcarce apparently ſerrulate, bluntiſh, roughiſh with very fine hairs along the edge and underneath. Flowers among the bundles of leaves, many, peduncled. Calyx four-cleft, ſmall, yellow, with the ſegments ſharp and bent back. Nectaries or petaloid ſcalelets upright, and ſo ſmall as hardly to be viſible to the naked eye. Stamens ſhorter by half than the calycine ſegments, and upright. Stigma commonly bifid, more rarely trifid, longer than the ſtamens. Flowers always hermaphrodite, ſometimes five-cleft and five-ſtyled. The ſmell of the flowers as in thoſe of *Prunus Padus* or Bird Cherry. Berry oblong, ſmall, black, two-ſeeded.

Native of Siberia, about the river Terec, &c. The wood is white on the outſide, but within of a ruſſet colour with teſtaceous bands, the hardneſs of a bone [e].

5. This is an upright ſhrub, with branches becoming thorny at the end. Leaves ſtiffiſh, perennial, lanceolate or ovate, blunt, even, petioled, paler and netted underneath, having frequently a very ſhort point at the end. Flowers axillary, each on a pedicel ſhorter than the leaf. Berry juiceleſs, with a groove on each ſide, ſubbilobed, two-valved, two-celled, with one ſeed in each cell. Seed oblong, convex, ſubtriquetrous. There are two varieties; one with ſmaller leaves, ovate or ovate-oblong, like thoſe of Box, the other with linear-lanceolate leaves [f].

According to Linneus it is leſs than *R. catharticus*, which it otherwiſe reſembles. Leaves at the buds two or three, like thoſe of the Olive but ſmaller, even, of a firm ſubſtance, quite entire, edged as it were with veins, on ſhort petioles, bluntiſh, netted. Fruits ſolitary, reſembling thoſe of the firſt ſpecies.

Native of Spain and Barbary.—Introduced in 1776, by Caſimir Gomez Ortega, M.D.

6. Native of the iſland of Teneriffe, where it was found by Mr. Francis Maſſon, and introduced in 1788 [g].

7. This ſpecies bears ſo much reſemblance to the firſt, that it might be almoſt conſidered as a variety, were not all the flowers hermaphrodite, and ſome trifid, others quadrifid, in equal numbers, with ſtamens correſponding to theſe diviſions. The leaves are narrower and much ſmaller, attenuated to both ends, and of an oval form. The principal branches are procumbent. The ſpines are more frequent. The berry is roundiſh, black, and contains three whitiſh ſeeds, each incloſed in a dry whitiſh membrane, ſeparating into two parts with elaſtic force [h].

According to Villars, it is a very low ſhrub, much branched, forming an impregnable buſh, by preſenting its thorns every way.]

Mr. Miller ſays, that his *R. longifolia* grows to a larger ſize than his ſecond, which is the *R. infectorius*, but not ſo high as the firſt, or *R. catharticus*. The branches are ſtronger, and armed with a few long ſpines; the leaves are like thoſe of the wild Plum, but a little longer and narrower; the flowers are ſmall, of a yellowiſh colour, and produced from the ſide of the branches: they appear in june, but are not ſucceeded by berries in this country.

[Haller, from Duhamel, conſiders theſe berries as the *Graines d'Avignon*, which are preferred to thoſe of the common ſort in dyeing. The Maroquin or Morocco leather is dyed yellow with them.

Native of Switzerland, Auſtria, the South of France and Italy. Introduced in 1775, by the Doctors Pitcairn and Fothergill [i]: by which I ſuppoſe that the author of the Kew catalogue did not allow the *longifolia* of his maſter to be the *R. ſaxatilis* of Linneus.

8. This is a ſhrub or ſmall tree, creeping by runners. Branches round, ſtriated, alternate, remote, divaricating at an acute angle. Leaves alternate, petioled, bluntiſh, very finely and acutely ſerrate, even, alternately veined, at the baſe of the branchlet often oppoſite. Spikes terminating ſimple or alternate, in a naked panicle. Flowers interruptedly glomerate, ſeſſile, cluſtered, minute. Corolla five-cleft. Stamens five, within the petaloid ſcale. Style ſhort. Stigma triple [k].

According to Oſbeck, this ſhrub grows a fathom in height, with leaves like thoſe of the common Tea; the flowers are very ſmall, and reſt on the top of the boughs, which are again ſubdivided into ſmaller branches. The poor in China, where it is a native, make uſe of the leaves inſtead of the true tea. They call it *Tia*.

9. This tree riſes generally to a very conſiderable height: the trunk is often above two feet and a half in diameter, and covered with a thick ſcaly bark. The wood is hard, of a dark colour and cloſe grain: it is looked upon as one of the beſt timber-woods in the iſland of Jamaica, where it grows naturally in many parts [l].

10. Branches round, ſcattered, ſmooth, with an aſh-coloured bark. Leaves petioled, alternate, an inch and more in length, very finely nerved and veined, quite ſmooth on both ſides, blunt. Umbels axillary on very ſhort peduncles. Pedicels ſmooth, a little longer than the common peduncle.

Native of the iſland of Santa Cruz, whence it was ſent by v. Rohr and Weſt.

11. Branches round, ſcattered, ſmooth, with an aſh-coloured bark. Leaves petioled, alternate, an inch and half long, quite ſmooth, paler and yelloviſh at the edge, eſpecially the younger ones, blunt, above ſcarcely veined, beneath paler, veinleſs and nerveleſs. Peduncles two or three together, very ſhort, ſmooth, one-flowered. Flowers ſmooth. Germ oblong, ſmooth.

[d] Cavanilles. [e] Pallas. [f] Desfontaines.

[g] Hort. kew. [h] Jacqu. vind. [i] Hort. kew. [k] Linn. mant. [l] Browne.

Digitized by Google

Style one, with a bifid ſtigma.—Weſt ſent it from the ſame iſland [m].

12. This was found at the Cape of Good Hope by Thunberg [n].

13. Branches ſlender, tomentoſe above, hoary. Leaves petioled, alternate, ſcarcely an inch in length, gradually leſs and leſs upwards, on the upper ſurface ſmooth and ſomewhat wrinkled, mucronate. Petioles very ſhort, tomentoſe. Flowers ſubſolitary, ſcarcely peduncled, aſh-coloured, ſubtrigynous.—Suppoſed to be a native of New Zealand [o].

14. This is the *pumilus* of Cavanilles, but it is very different from the *pumilus* (n. 20.) of Jacquin and Linneus's mantiſſa, both in flower and fruit; the leaves alſo are ſmaller, ſubcrenate, and on very ſhort petioles [p].

Native of the kingdom of Valentia.

This is a ſmall ſpecies, growing in calcareous rocky places, and is never upright, but always repent as it were or ſpread upon the bare rock; it is very branchy and the branches are tortulous. The twigs are limber, and the wood hard and whitiſh: the bark of a reddiſh brown, ſmooth, but tuberculated here and there with knots and fiſſures. The leaves on the young branches are ſcattered and approximated, ſtanding on very ſhort footſtalks, and are ovate, ſcarcely ſerrated, with diſtant ſerratures, and ſometimes without any: they are of a gloſſy or bright green above, and paler beneath: the ſtipules are ſhort and deciduous. The flowers are axillary, numerous, ſeated on capillary footſtalks, which at length bend, and are furniſhed with a ſmall reddiſh deciduous bracte. The calyx is of an herbaceous colour with a caſt of yellowiſh, and is funnel-ſhaped, with a quadrifid border, with acute diviſions, from which proceed ſo many extremely ſhort ſtamens, ſeated rather below. There is no corolla, unleſs the calyx be ſo named. The filaments are ſhorter than the calyx, ſubulate, and whitiſh: the anthers ovate, yellow, and twin. Germ ovate, in the bottom of the calyx; ſtyles three: ſtigmas thickened. The fruit is an ovate trigonal capſule, and the ſeeds, which are three in number, are three-ſided [q].

This ſhrub flowers in may in Spain, and perfects its fruit in june, growing in company with the Rhamnus lycioides and Alaternus, Arbutus Unedo, &c. &c.

15. This is a ſmall upright tree, ſeven feet high, branching, and in habit approaching near to *Viburnum Lantana*. Leaves ovate, very blunt, tomentoſe on both ſides, petioled, alternate, four inches long. The petals, when examined by a magnifier, appear ciliate. It has the flower and fruit of the next ſpecies; and abounds in coppices, on the coaſt of the iſland of Cuba.

16. This alſo is an upright tree, with moſt of the branches ſpreading out horizontally. The twigs, petioles, peduncles, lower ſurface of the leaves, and outer ſurface of the calyx are covered with a ſlight ferruginous nap. Leaves oblong-ovate, acute, entire, the upper ſurface ſmooth and ſhining, alternate, for the moſt part diſtich. Racemes ſhort, corymbed, axillary, ſeven-flowered or thereabouts. Flowers without ſcent, all pointing upwards, with greeniſh ſcales. Calyx deeply five-cleft. Anthers ſtanding out beyond the ſcales. Style ſingle, ending in a trifid ſtigma. Capſule roundiſh, three-grooved, three-celled, three-valved; the valves opening two ways at the top. Seeds ſolitary, roundiſh, flatted a little, emarginate, black and very ſhining. In high mountain woods it attains the height of twenty feet, whilſt in coppices on the coaſt it is rarely ſeven feet high, with leaves four inches long: whereas in the former they are half a foot in length. The nap in Cuba is ſilvery, in the other iſlands always ferruginous. In the iſland of Martinico the French know it by the name of *Bois couleuvre* or Snake-wood; whence the trivial name.

Native of ſeveral iſlands in the Weſt Indies, where it flowers in january, june and november [r]: probably the greateſt part of the year. Here it flowers in june; and was introduced from the Bahama iſlands, in the year 1726, by Mr. Mark Cateſby [s].

The petals are lanceolate from the ſinuſes of the calyx: the ſtamens within the petals: a tranſverſe nectariferous callus within the baſe of the ſtamens: the ſtyle three-ſided [t].]

Miller deſcribes his *Ceanothus arboreſcens* as riſing with a ſhrubby ſtalk eighteen or twenty feet high, ſending out ſeveral horizontal branches; the leaves ovate and veined; the flowers axillary, on very ſhort peduncles, of a white herbaceous colour, and ſucceeded by dry capſules, ſhaped like thoſe of *Ceanothus americanus*.

[17. Stem ſhrubby, twining, ruſeſcent, even. Leaves alternate, quite entire, repand, even; on roundiſh, rufous, inarticulate petioles [u].

Native of Carolina. Cultivated in 1714, by the Dutcheſs of Beaufort. It flowers in june and july [x].

18. This is a ſmall tree, reſembling *R. catharticus* very much, but taller, buſhy, with thicker branches, leſs ſpreading, and never having any thorns. Trunk often the thickneſs of the human arm; the wood pale red, of a brighter colour than in the common Buckthorn. Branches ſtraight, teſtaceous-hoary, even: the twigs moſtly oppoſite, leafy at the end. Leaves larger, more oblong, ſubacuminate, more ſharply ſerrate than in *R. catharticus*, and veined in a different manner; always ſmooth, and on longer petioles. Flowers greeniſh-yellow, not larger than in *R. catharticus*: the leaflets acute and deciduous. Stigma twin. Berries among the leaves on peduncles equal to the petioles; they are the ſize of a large pea, frequently twin, and commonly two-ſeeded; the rudiment of the third ſeed being abortive.—Gmelin in Ammann has erroneouſly deſcribed the fruit as red, and the flowers as white. In the *Flora Sibirica* he has ſet it down as a variety of *R. catharticus*, although it differs from it as much nearly as *R. ſaxatilis*, which indeed it reſembles more in the nervature and circumſcription of the leaves.

Native of Dauria, by the river Argun, where it is plentiful; but neither this nor the common Buckthorn occur in other parts of Siberia [y].

19. This forms a ſhrub of ſeveral feet in height. The rounded leaves, manifeſtly crenate all about, diſtinguiſh it eaſily from *R. Frangula* [z], (n. 21.) Theſe leaves are not doubly-crenate: in the younger ones, the margin, being plaited by prominent veins, has the appearance of doubled notches [a].

The calyx and ſtigma are four-cleft, as in *Rh. catharticus* [b].

Native of the mountains of Germany, Switzerland, the South of France, and Piedmont.

20. This differs from the next ſpecies by its ſtems adhering to the rocks, and by its ſerrate leaves; from the preceding by its hermaphrodite flowers [c]. The leaves are ſcarcely villoſe underneath. The berries are three-ſeeded. It roots itſelf in the fiſſures of the rocks, and covers them like Ivy [d]. Hence Scopoli's trivial name of *rupeſtris*. He ſays, that the leaves are ſcarcely an inch in length, with the edges whitiſh, ſomewhat cartilaginous, and obſcurely notched; having a ferruginous nap on the nerves underneath. The flowers are four or five-cleft, with the calycine ſegments ſomewhat toothletted. Petals and ſtamens white.

Native of Germany, Carniola, Dauphiné, Monte Baldo, Spain.]

21. The black berry-bearing Alder riſes with a woody ſtem to the height of ten or twelve feet, ſending out many irregular branches, covered with a dark bark. Leaves ovate-lanceolate, about two inches long, and an inch broad, having ſeveral tranſverſe nerves from the midrib to the ſides. The flowers are produced in cluſters at the end of the former year's ſhoots, and alſo upon the firſt and ſecond joints of the ſame year's ſhoot, each upon a ſhort ſeparate pedicel; they are ſmall, of an herbaceous colour, and are ſucceeded by ſmall round berries, which turn red, but are black when ripe. The flowers appear in june, and the berries ripen in ſeptember.

[m] Vahl. [n] Linn. ſuppl. [o] Vahl. [p] Willdenow. [q] Cavanilles. [r] Jacquin. [s] Hort. kew. [t] Linn. ſyſt. [u] Linn. ſuppl. [x] Hort. kew. [y] Pallas roſſ. [z] Villars. [a] Willdenow. [b] Linn. [c] Idem. [d] D'Aſſo.

Digitized by Google

[In its wild ſtate, it is ſeldom much more than four feet high, with numerous forked branches. Leaves on the young branches only, oppoſite, petioled, obovate or elliptic-lanceolate, pointed, quite entire, ſmooth, veined, of a bright pleaſant green. Peduncles axillary, two or three together, one-flowered. Calyx cup-ſhaped, with five reflexed ſegments, between which ſtand the little petals, and oppoſite to them the very minute ſtamens, with dark-purple anthers. Germ ſuperior, with a very ſhort ſtyle, and a bifid ſtigma. Berry dark-purple, with two hemiſpherical ſeeds [e].

Mr. Relhan remarks that it has deciduous bractes; that the calyx has brown, remote binate and ſolitary villoſe hairs; that the ſtyle is ſhorter than the calyx, with an emarginate ſtigma; and that the berry has two, or ſometimes, but rarely, three ſeeds.

According to Scopoli, the berry is three-celled, and the ſize of thoſe of Juniper; one ſeed in each cell, ovate, yellow, compreſſed; and one of the three ſometimes leſs or even entirely abortive.

Gærtner deſcribes the berry as globular, ſmooth, dark-coloured, ſucculent, two-celled, or ſometimes, but ſeldom three-celled, with a very thin partition which almoſt diſappears when the berry is ripe. Seeds ſolitary, ovate-rounded, plano-convex, or very obtuſely angular on the inner ſide, produced at the baſe into a cartilaginous and very turgid umbilicus, ſmooth and rufeſcent. This ſtructure of the umbilicus occurs ſcarcely any where except in *Phylica*.

Native of moſt parts of Europe, in woods, thickets and hedges; alſo in Siberia: flowering with us early in may, and ſometimes in april.

From a quarter to half an ounce of the inner bark, boiled in ſmall beer, is a ſharp purge. In dropſies or conſtipation of the bowels in cattle, it is a very certain purgative. The berries are alſo purgative, like thoſe of common Buckthorn. Theſe, gathered before they are ripe, dye wool green and yellow—when ripe, blue-gray, blue and green. The bark dyes yellow, and with preparations of iron, black. The flowers are particularly grateful to bees. Goats devour the leaves voraciouſly; and ſheep will eat them. Charcoal prepared from the wood is preferred by the makers of gunpowder [f].

The berries of this ſpecies, and alſo of the Cornel, are ſaid to be brought to market for thoſe of Buckthorn. They are eaſily diſtinguiſhed; the true Buckthorn having four ſeeds, this two; and the *Cornus* one nut incloſing two kernels [g].]

β. This has larger and rougher leaves. It grows naturally on the Alps and other mountains of Europe. Perhaps *R. alpinus*.

γ. Is of humble growth, ſeldom riſing above two feet high. It grows on the Pyrenees. [Perhaps *R. pumilus* is here intended.

22. This reſembles *R. Frangula* very much, but is larger. The calyxes are villoſe, whereas in that they are ſmooth. The petaloid ſcalelets are ſeſſile; in that they have ſhort claws [h].

Native of the Azores: where it was found by Mr. Francis Maſſon, and introduced by him in 1778. It flowers in july.

23. Native of Madeira and the Canary iſlands. Found by Maſſon, and introduced in 1785 [i].

24. This is a ſhrub, becoming in a manner a tree. Branches round, alternate, rod-like, often reclining or ſpreading, covered with a ſmooth brown bark. Leaves alternate, blunt, nerved and veined: nerves approximating: petioles round, filiform, longiſh, ſmooth. Peduncles ſhorter than the petioles, round, ſmooth, many-flowered: flowers pedicelled diſpoſed in a little umbel, whitiſh-green. There are a few minute ſcales at the baſe of the umbels. Calyx cut round at the baſe: border five-cleft, deciduous; ſegments ovate, ſpreading. Petals or ſcalelets inſerted between the ſegments of the calyx, minute, vaulted. Filaments the length of the petals, and concealed under them. Germ roundiſh, placed at the baſe of the calyx or on the receptacle. Style three-parted to the baſe. Stigmas blunt. Fruit placed at the baſe of the calyx, ſubtricoccous, three-celled, covered with a juiceleſs ſkin, and when that burſts, diviſible into three parts, like thoſe of a capſule, opening within and at the top; with membranaceous partitions. Seeds ſolitary, oblong, flatted a little, ſmooth, black. The fruit, when ripe, and without the ſkin, being cut tranſverſely above the middle, appears to be tricapſular and ſex-valvular.

It is very nearly allied to *R. colubrinus*, but that has the branchlets, petioles and peduncles ferruginous-tomentoſe; the ſtyle three-ſided, trifid only at the top [k].

On account of the juiceleſs fruit, and the vaulted petals, L'Heritier refers this ſpecies to the genus *Ceanothus*: but at the ſame time he thinks that all the *Ceanothi* might better be removed into this genus. On the contrary Swartz will not by any means conſent to this plant being conſidered as a *Ceanothus*; its whole habit being that of *Rhamnus*, and the fruit of ſeveral other ſpecies in this genus being of the ſame ſtructure with this.

Browne calls it ſhrubby Rhamnus with bilocular berries: but in the figure, the fruit ſeems to be tricoccous.

Native of the iſlands of Jamaica, and St. Bartholomew. Cultivated in 1758, by Mr. Miller. It flowers in auguſt.

25. Native of the Cape. Cultivated before 1779, by Robert Edward Lord Petre [l].

26. Stem ſhrubby, round, ten feet high, weak, climing by tendrils. Leaves alternate, on very ſhort petioles, blunt with a minute point, quite entire, ſmooth above, ſomewhat hairy underneath, an inch in length. Tendrils from the upper axils, ſolitary, ſimple. Stipules at the baſe of the branchlets, awl-ſhaped, caducous, three lines in length. Flowers umbelled, axillary. Calyx one-leafed, herbaceous, ſlightly pubeſcent on the outſide. Tube turbinate, two lines in diameter. Border five-parted; ſegments from a broad baſe ovate, acute, ſpreading very much, a line in length. Petals five, inſerted into the margin of the receptacle between the ſegments of the calyx, whitiſh, boat-ſhaped, convolute at the ſides, incloſing the ſtamens, diverging, ſhorter than the calyx. Filaments five, inſerted within the baſe of the petals, filiform. Anthers roundiſh, ſmall. Germ immerſed in a ſnow-white receptacle, filling the tube of the calyx. Style three-ſided, green, ſhort. Stigma trifid.

Native of Africa, where it was found by James Bruce, Eſq. It was introduced in 1775, and flowers in november [m].

27. In appearance this approaches to *R. alpinus*; but the leaves are more looſely nerved, more netted, and only ſmooth but not ſhining as in that [n]. Monſ. L'Heritier ſets it down as a native of North America; but in the Kew catalogue no place of growth is aſſigned to it. There it is ſaid to have been introduced in 1778, by Meſſ. Lee and Kennedy; and to flower in may.

28. Trunk ten or fifteen feet high, with a ſmooth bark. Branches ſubdivided, ſpreading. Leaves alternate, acuminate, unequally ſerrate, nerved, ſmooth on both ſides, very finely veined. Petioles roundiſh, ſmooth. Peduncles axillary, the length of the petioles, ſhort, upright, many-flowered; flowers pedicelled, ſmall, green, or yellowiſh. Stipules ſmall, acuminate, at the baſe of the peduncles. Calyx ovate and cut round at the baſe, permanent, five-cleft: ſegments acute, ſpreading, thickiſh, deciduous. Petals very minute, placed between the diviſions of the calyx on very ſhort pedicels, concave. Filaments five, ſhorter than the calyx. Anthers roundiſh, three-cornered, covered at the back by the petals. Germ roundiſh, at the bottom of the calyx. Style ſhorter than the ſtamens, trifid. Stigmas blunt, contiguous. Berry ſpherical, ſometimes three-grooved at the top, the ſize of a ſmall pepper-corn, placed on the calyx, pellucid, pale green, containing from one to three

[e] Smith. [f] Withering. [g] Engl. bot. [h] L'Heritier. [i] Hort. kew. [k] Swartz. [l] Hort. kew. [m] Idem. [n] L'Heritier.

oblong

Digitized by Google

oblong three-cornered ſeeds.—Native of Jamaica, in the more temperate parts, in mountain coppices; flowering in auguſt, and ripening the berries in october [o].

29. Monſ. L'Heritier informs us, that he obtained this ſpurious plant above ten years ſince, (about 1778) from the ſeeds of *R. alpinus*; that he obſerved the mother, what was abſolutely female, and ſeparated from any males, every year; that *R. Alaternus* was certainly the father; and that ſeeds ſown abundantly in ſome provinces of France conſtantly produced this ſpurious plant, without ever varying. It has ſomething from both parents; as the herb of the mother; the leaves between both, but in ſubſtance approaching more to *Alaternus*, and almoſt perennial; and the androgynous flowers of the father, not dioecous, as in the mother.

30. Stem ſhrubby, round, very even, ſmooth, ſhining, branched, eight feet long, procumbent; with many, ſcattered, ſolitary, ſtraight, ſhort prickles. Leaves notched a little, flat, ſmall, ſmooth, alternate, ſtreaked with many oblique parallel lines. Flowers white, minute, on many-flowered ſubterminating peduncles. Calyx five-toothed very ſmall. Corolla inferior: petals ten, lanceolate, equal, upright; the five inner ones embracing the ſtamens. Filaments five, awl-ſhaped, the length of the corolla; with nodding anthers. Germ ovate, rugged. Style filiform, equal to the ſtamens. Stigma thickiſh, concave. Fruit (a Drupe) ſmall, oblong-ovate, rugged, red; containing an oblong, two-grooved, two-celled nut [p].—Loureiro would give the ſpecific difference thus: prickles ſolitary, ſtraight; leaves ovate, obliquely marked with lines; peduncles many-flowered.

Burman has given a figure of it from Herman's ſpecimen; which has ſlender, flexile, ſubhirſute branches, putting forth ſmaller branchlets alternately; theſe latter are ſimple, and have leaves on each ſide, which are alternate, ſmooth, ovate, half an inch long, quite entire, having oppoſite veins, and on petioles a line in length: at the baſe of each leaf is a rigid prickly ſcale. Flowers axillary, ſolitary, bay-coloured, four-petalled, on peduncles no longer than the petioles. Berry black, three lines in diameter.

Oſbeck ſays, that it often grows to the height of a man, and is remarkable for its ſmall and beautiful leaves, of a yellow-green colour beneath, with red veins. The anthers are black. When he firſt ſaw it in China, he ſuppoſed that it had eſcaped the notice of preceding botaniſts.—Native of China, Cochinchina and Ceylon.

31. The Alaternus is a ſhrub with alternate, ſhining, evergreen leaves, ovate, ovate-lanceolate, or lanceolate, often glandular at the baſe, having remote ſerratures about the edge. Flowers ſmall, numerous, axillary, in ſhort blunt racemes. There is a very ſmall bracte at the baſe of each pedicel. Flowers male and female or imperfect hermaphrodites, on the ſame or different individuals. The calyx in both ſorts five-cleft, with the ſegments ovate, ſpreading, often bent down, yellow or browniſh. Corolla none. In the male flowers, five upright ſtamens, alternate with the ſegments of the calyx: in the others, the rudiments of five ſtamens; the ſtyle three-parted; the berry ſmall, round, from red turning blackiſh when ripe, having two or three ſeeds, convex on one ſide, angular on the other [q].

Willich obſerves that the Alaternus is never perfectly dioecous; but that in ſome ſhrubs moſt of the flowers have perfect ſtamens, with a ſingle imperfect ſtyle; having however a very few flowers mixed with them, which at the bottom of the calyx have an ovate-three-cornered germ, with a ſemitrifid ſtyle, twice the length of the ſtamens. In other ſhrubs, moſt of the flowers have ſtamens, and a trifid or very rarely a quadrifid ſtyle, with a very few flowers mixed with them, having a ſingle imperfect ſtyle.—Thus impregnation is frequently carried on in plants ſuppoſed to be dioecous, when one of the ſexes is preſumed to be abſent; and on this foundation are ſome of the beſt objections to the ſexual ſyſtem ſupported.

[o] Swartz. [p] Loureiro. [q] Desfontaines.

Native of the South of Europe, and of Barbary. The freſh branches or young ſhoots with the leaves will dye wool a fine yellow. The honey-breathing bloſſoms, ſays Mr. Evelyn, afford an early and marvellous relief to the bees. They come out in april.

This gentleman informs us, that he was the firſt who brought the Alaternus into uſe and reputation in this kingdom, and that he had propagated it from Cornwall to Cumberland.

This boaſt of Mr. Evelyn's muſt be underſtood of his bringing this ſhrub into general uſe: for Parkinſon, in 1629, had ſaid, that we have growing in our country the tree called *Alaternus*. It was however then rare: for Parkinſon adds—"the beauty and verdure of the leaves, abiding ſo freſh all the year, doth cauſe it to be of the greater reſpect, and therefore findeth place in their gardens only, that are curious conſervers of all nature's beauties." He calls it *Evergreen Privet*, which name is now loſt in the Latin one.—Gerarde ſays, it is a ſtranger in England; and Johnſon (in 1633) does not contradict it.

Cluſius reports, that the fiſhermen in Portugal dye their nets red with a decoction of the bark; and that dyers there uſe ſmall pieces of the wood to ſtrike a blackiſh blue colour.]

Mr. Miller makes four ſpecies of *Alaternus*, and has figured two in his plates. Theſe are the only varieties worth conſidering. The firſt (α) has a variety with variegated leaves, commonly called bloatched Phillyrea by the nurſery-men: and the third (β) has the leaves ſtriped with white and with yellow, called ſilver and gold-ſtriped Alaternus.

β. has the leaves much longer and narrower, and the ſerratures on the edges much deeper: this ſhoots its branches more erect, forms an handſomer buſh, and is equally hardy.

The Phillyrea is ſometimes confounded with the Alaternus, by ſuch as are not botaniſts; but they may eaſily be diſtinguiſhed by the poſition of their leaves, which are alternate in this, but placed oppoſite by pairs in that.

The Alaternus was much more in requeſt formerly than it is at preſent; having been planted againſt walls in court-yards to cover them, as alſo to form evergreen hedges in gardens; for which purpoſe it is very improper, for the branches ſhoot very vigorouſly, and being pliant are frequently diſplaced by the wind; in winter, when much ſnow falls in ſtill weather, the weight of it often breaks the branches; theſe hedges alſo muſt be clipped three times in a ſeaſon to keep them in order, which is both expenſive, and occaſions a great litter in a garden.

[This ſhrub is ſtill ſometimes uſed in towns for concealing walls; but chiefly to make a variety in ornamental plantations.

32. Stature of the Elm or Hornbeam; and it may perhaps be of the ſame genus with the latter. Roots horizontal, diffuſed. Trunk ſtraight, very much branched and forming a kind of buſh, with the branches extending frequently to twenty paces, and to a conſiderable height; two fathoms in circumference. The wood white and brittle; the bark brown, entire, covered with a whitiſh-gray ſkin. Branches and branchlets ſlender, ſpreading. Leaves alternate, ſtiffiſh, on very ſhort petioles, ſmalliſh, ſpreading, ovate, acute, the interſtices between the notches rounded, duſky green above, paler and netted underneath, in thickets rugged, very ſmooth in higher ſituations. Fruit at the ends of the branchlets, axillary, ſeſſile, ſolitary, naked, dry, two-celled, globular-acute, more gibbous on one ſide.

The genus of this tree is yet uncertain, the flowers not having been obſerved, nor the fruit in a ripe ſtate, by any botaniſt.—Native of Siberia [r].]

33. This tree riſes with a pliant ſhrubby ſtalk to the height of eight or ten feet, ſending out many weak ſlender branches, garniſhed with oval leaves placed alternately, ſtanding upon foot-ſtalks near one inch long; theſe have three longitudinal veins, and are of a pale green. The flowers come out at the

[r] Pallas.

wings

Digitized by Google

wings of the ſtalk in cluſters, almoſt the length of the young branches; they are of a greeniſh yellow colour, and appear in june, and are ſucceeded by broad, roundiſh, buckler-ſhaped ſeed-veſſels, which have borders like the brims of a hat, the foot-ſtalks being faſtened to the middle; theſe have three cells, each containing one ſeed.

[From this ſingular appearance of the fruit, like a head with a broad-brimmed hat on, the French call it *Porte chapeau*.

According to Pallas, it is a buſhy tree, of the ſame ſtature with *Prunus ſpinoſa*, very much branched from the bottom. Branches round, ſpreading, tough, brown, alternately, ſubdivided, with ſingle or double prickles, recurved and very ſharp, at each diviſion and bud. Leaves alternate petioled, rounded ovate, unequal at the baſe, three-nerved, very obſcurely ſerrulate or entire, ſmooth. Racemes by the ſide of the petioles axillary, ſhort, corymbed, divaricating, compoſed of from eight to thirty flowers, one or two only of which are fertile. Calyx one-leafed, flat, five-cleft, with lanceolate yellow ſegments. There is a nectariferous crown between the calyx and the germ which is ſubſinuate, and five petaloid bodies between the ſtamens and the ſegments of the calyx. Stamens five, bent back, with oblong anthers. Germ depreſſed, with three very ſhort ſtyles, terminated by reflexed ſtigmas. The fruit ſprings from the augmented crown of the germ, and is diſcoid, peltate, corticoſe when ripe: it contains one bony orbicular ſeed, flat above and conical beneath.

Desfontaines deſcribes it as a very branching ſhrub; the branches twiſted and reclining. Prickles in pairs, one ſhorter than the other and recurved. Leaves cordate-ovate, three-nerved, ſerrate, ſmooth. Flowers yellow, numerous, aggregate, axillary; on ſhort filiform pedicels. Petals bagged, minute, ſpreading and bent down. Stamens incloſed in the petals. Fruit a juiceleſs drupe, crowned with a membranaceous, wide, waved, horizontal, permanent margin; three-celled, with one ſubovate compreſſed ſeed in each cell.

Willich remarks, that the ſegments of the calyx, ſcalelets or petals and ſtamens are commonly five, but that nevertheleſs ſome flowers have only four; there are however always three ſtyles.

Native of the South of Europe, the Levant, Caucaſus and Barbary.]

This is by many perſons ſuppoſed to be the plant, from which the crown of thorns which was put upon the head of our Saviour, was compoſed; the truth of which is ſupported by many travellers of credit, who affirm that this is one of the moſt common ſhrubs in the country of Judæa; and from the pliableneſs of its branches, which may eaſily be wrought into any figure, it may afford a probability.

[Haſſelquiſt is of opinion that it was rather another ſpecies (n. 42.); called therefore by Linneus *Rhamnus Spina Chriſti:* but a modern Right Reverend Commentator inclines to think that the crown was not of thorns, but of the ſoft Acanthus, or *Bear's-foot*; he ſhould have ſaid *Bear's-breech*, for the Bear's-foot is the Hellebore. I muſt own that his reaſoning does not appear to me to make out his point.

34. The true Lotus of the Lotophagi is a very branching ſhrub; the branches are reclining and flexuoſe. Prickles in pairs at the origin of the leaves, one ſtraight, the other ſhorter and bent in. Leaves alternate, ſmall, blunt, three-nerved, ſmooth, ſomewhat rigid, on very ſhort petioles. Flowers ſolitary or glomerate, axillary, each on a ſhort pedicel. Calyx five-parted; ſegments ſmall, ovate, ſpreading, alternate with the petals; which are five in number, minute, half-funnel-form. Stamens five, oppoſite to the petals. Styles two, ſhort, approximating. Fruit a ſpherical drupe, the ſize of a wild plum, ſweet and harmleſs; incloſing a ſmall, round, bony, two-celled nucleus, firſt green, but when ripe tinged with ſaffron colour[t].

Linneus remarks, that the branchlets of this ſhrub are round; that one of the prickles is horizontal, the other recurved as in *Paliurus*; and that the leaves are as in Zizyphus, with reſpect to form, nerves, ſmoothneſs and ſize, only the edge is obſoletely and very thinly crenate.

Frequent on the banks of the leſſer Syrtis near Caſſa, Tozzer, Kerwan, &c. flowering early in the ſpring, and ripening the fruit in autumn[t]. Dr. Shaw found it long before Monſ. Desfontaines, in this country, which borders on that of the Lotophagi. Mr. Park diſcovered it towards the Niger and Senegal rivers; and Mr. Browne in Dar-Foor: ſo that we have it at the eaſtern as well as the weſtern extremity of the African deſert; and it appears, that it is diſſeminated over the edge of the great Deſert, from the coaſt of Cyrene, round by Tripoly and Africa proper, to the borders of the Atlantic, the Senegal and the Niger. Major Rennell ſaw the ſame kind of ſhrub and fruit, or what is exceedingly like it, in Bengal, where it is called *Byre*; and on the very banks of the Ganges, in dry ſituations. The people eat them there, as we may ſloes or wild berries.

Pliny deſcribes two ſorts of Lotus; the one found at the Syrtis, and among the Naſamones, &c. which is this; the other in Egypt which is *Nymphæa Lotus*. The former, he ſays, from Cornelius Nepos, is the fruit of a tree, in ſize ordinarily as big as a bean, of a yellow colour, ſweet and pleaſant to the taſte. The fruit was bruiſed, made into a kind of paſte, and then ſtored up for food. A ſort of wine was alſo made from it, reſembling mead; but it would not keep many days. Pliny adds, that armies in marching through that part of Africa, have ſubſiſted on the Lotus. Perhaps this may refer to the army of Balbus, which Pliny informs us, had penetrated to Gadamis and Fezzan.

Polybius, who had himſelf ſeen the Lotus, being employed by Scipio Africanus the younger, in exploring the coaſts of Africa; ſays, that it is the fruit of a ſhrub, which is rough and armed with prickles, and in foliage reſembles the Rhamnus; that when ripe it has the ſize of a round olive; has a purple tinge, and contains a hard ſtone; that being pounded it is laid by for uſe; and that its flavour approaches to that of figs or dates: finally, that a kind of wine is made of it by expreſſion, and diluted with water; that it affords a good beverage, but will not keep more than ten days.

Of modern travellers, Dr. Shaw ſays that the fruit is common in the deſerts, and other parts of Barbary; is ſtill in great repute, and ſold in the markets all over the ſouthern diſtricts of thoſe kingdoms. Monſ. Desfontaines relates, that it is ſpread over the ſouthern parts of the kingdom of Tunis, on the borders of the Deſert, and in the environs of the Leſſer Syrtis; that the fruit is ſold in the markets, their cattle fed with it, and a liquor drawn from it, as heretofore.

Monſ. Saugnier, who was ſhipwrecked on the coaſt of Africa in 1784, and was carried captive, along the weſtern border of the Sahara to Morocco; ſays, that between the Capes Bojador and Nun, the people with him, eat of nothing during the day-time, that is, on the way, but a ſmall wild fruit, reſembling the Jujube, which is to be found every where. This was about the middle or end of march. Briſſon, who was in like manner carried acroſs the Deſert, during the latter part of the ſummer and in autumn, only remarks abundance of prickly ſhrubs; probably the ſame, after the ſeaſon of fruit. Mr. Park mentions february and march as the ſeaſon, on the ſouth of the Deſert; Monſ. Desfontaines, ſays auguſt and ſeptember, to the north of the Deſert; and Mr. Browne, that the fruit remains dry on the tree, great part of the winter months.

Mr. Park deſcribes the fruit, as ſmall farinaceous berries, of a yellow colour, and delicious taſte. The natives, he ſays, convert them into a ſort of bread, by expoſing them ſome days to the ſun, and afterwards pounding them gently in a wooden mortar, until the farinaceous part is ſeparated from the ſtone. This

[t] Desfontaines.

[t] Desfontaines.

Digitized by Google

meal is then mixed with a little water, and formed into cakes, which, when dried in the ſun, reſemble in colour and flavour the ſweeteſt gingerbread. The ſtones are afterwards put into a veſſel of water, and ſhaken about, ſo as to ſeparate the meal which may ſtill adhere to them: this communicates a ſweet and agreeable taſte to the water, and with the addition of a little pounded millet, forms a pleaſant gruel, called *fondi*, which is the common breakfaſt in many parts of Ludamar, during the months of february and march. The fruit is collected by ſpreading a cloth upon the ground, and beating the branches with a ſtick.

Mr. Park ſays, that the Lotus is very common in all the kingdoms which he viſited; but is found in the greateſt plenty on the ſandy ſoil of Kaarta, Ludamar, and the northern parts of Bambarra, where it is one of the moſt common ſhrubs of the country. He had obſerved the ſame ſpecies at Gambia, and had an opportunity to make a drawing of a branch in flower. The leaves of the deſert ſhrub are however much ſmaller, reſembling in that particular thoſe repreſented in the engraving given by Monſ. Desfontaines [a].

Mr. Browne informs us, that the Arabic name of the Lotus is *Nebbek*, and that there are two ſpecies of it in Dar-foor; the largeſt of which is termed *Nebbek-el-arab*. There is a difference in their fruit, as well as in their external appearance. The one is a buſh, with leaves of dark green, not very different from thoſe of the ivy, but much thinner. It appeared to be the ſame with that which he had ſeen in the gardens of Alexandria. The other a tree, growing to conſiderable ſize, but having both the leaves and fruit ſmaller; and the fruit of darker colour, and ſomewhat different flavour. Both of them equally thorny. The natives eat the fruit freſh or dry; for it dries on the tree, and ſo remains great part of the winter months. In that ſtate it is formed into a paſte of not unpleaſant flavour, and is a portable proviſion on journies [z].

Thus by comparing the information to be derived from ancients and moderns, collected with ſo much diligence, and digeſted with ſo much accuracy by Major Rennell, we are no longer left to wander in the wilds of conjecture, but are enabled to aſcertain without ambiguity that *Lotus*, the hiſtory of which Homer and other ancients mixed with fable; Herodotus mentioned, without having ſeen it, and Polybius deſcribed ſo well from his own knowledge.

The *Lotophagi*, as the Greeks called them, poſſeſſed a conſiderable part of the ſea coaſt between the two Syrtes, the iſland of Meninx, (now Jerba) and the coaſt beyond it, as far as the lake and river of Tritonis, to the Machlies. Scylax extends the name to the tribes generally, between the two Syrtes. Ptolemy limits them to the neighbourhood of the river Cinyps alone; whilſt Herodotus appears to confine them to the weſt of that river. Strabo places them in the iſland of Meninx alone: although he calls the adjoining Syrtis, that of the Lotophagi. Pliny, aſſigns them, in addition to the iſland, the environs of the Syrtis alſo.

But the allotment of this confined ſpace, alone, to the eaters of Lotus, was owing to a want of a more extended knowledge of the countries that border on the Deſert: for it appears, that the tribes who inhabit them, and whoſe habits are in any degree known to us, eat univerſally of this fruit, in a greater or leſs degree, according to circumſtances; and moſt of them, apparently, as much as they can obtain of it [r].

This tree cannot be the Λωτος of Theophraſtus, or the *Lotus* of Virgil; that is more likely to be the *Celtis* or Nettle-tree, which is accordingly named *Lotus* by Bauhin and others. Linneus has given the generic term of *Lotus* to a ſet of plants, moſtly herbaceous, of the leguminous tribe, and of his claſs Diadelphia. To the true Lotus, and the aquatic Lotus of Egypt, he has this name as a trivial. See the two articles of LOTUS and NYMPHÆA LOTUS, in this Dictionary. In the former of theſe articles, diſtinguiſh the Lotus of Theophraſtus and Virgil from this of Homer, Pliny, Polybius, &c. and correct what is there ſuggeſted of the Rhamnus Spina Chriſti being the true Lotus, by what has been detailed above. A very ſatisfactory account of the aquatic Lotus of Egypt, (Nymphæa Lotus) and of that of the Eaſt Indies, (Nymphæa Nelumbo) is given by Rennell, in his elaborate examination of the Geographical Syſtem of Herodotus.

35. This is a tree with ſubvilloſe branches. Leaves alternate, narrower towards the baſe on the hinder ſide, bluntiſh, ſmooth, three-nerved, petioled, yellowiſh. Corymbs ſolitary, ſhorter than the leaf, lateral, next the petiole. Prickles oppoſite to the peduncle, very ſhort, black, recurved, very ſharp, having frequently two points, one below the other [a].

Willdenow remarks, that the younger leaves are ſomewhat hairy about the edges; and that the younger branches are pubeſcent.—Native of the iſlands of Ceylon, and Amboyna.

36. This is a tree with round branches. Leaves very finely ſerrate, three-nerved, at the baſe on one ſide narrower, retuſe, and there more deeply crenate, petioled. Flowers very many, axillary, each on very ſhort pedicels, five-cleft, five-ſtamened; ſtyle bifid. Cloſe to the petioles is a very ſmall recurved prickle; but ſometimes this is wanting [a].

Loureiro deſcribes it as a middle-ſized tree, with twiſted ſpreading branches, and recurved prickles uſually ſolitary. Leaves ovate, quite entire, three-nerved, alternate. Flowers pale, axillary; on ſhort, aggregate peduncles. Fruit a middle-ſized drupe, ovate, red, ſweet, and eatable:—the ſtone ovate-globular, muricate with tubercles, having at the baſe a tranſverſe prominent acuminate callus, and conſtantly two-celled [b].

Native of the Eaſt Indies. Cultivated in China and Cochinchina: here by Mr. Miller in 1731 [c].] He ſays, that it riſes with ſhrubby ſtalks ten or twelve feet high, ſending out many ſlender branches, which have a yellowiſh bark, and are armed with ſingle recurved thorns (prickles) at each joint. Leaves round, heart-ſhaped, about two inches in length and breadth, and indented at the foot-ſtalk; they have three nerves, and are covered with a yellowiſh down on their under ſide. The flowers come out in cluſters from the wings of the branches; they are ſmall, of a yellowiſh colour, and are ſucceeded by oval fruit about the ſize of ſmall olives, incloſing a ſtone of the ſame ſhape.

[37. This is a tree ſcarcely higher than a man. Branches from a pellicle of whitiſh cotton, armed very thinly with ſmall ſolitary recurved prickles under the petiole. Leaves broad-ovate, often approaching to cordate, not ſeldom oblique, unequally ſerrate, duſky above, but underneath covered with a very fine white nap. Corymbs peduncled. Calyxes tomentoſe. Fruit a dry drupe, larger than a Cherry, inſipid, ſubaſtringent, with an unequal nut or ſtone [d].

It reſembles the preceding very much, but the fruit is the ſize of a Cherry or little bigger and inſipid. The prickles are fewer [e].

Native of the Eaſt Indies, in deſerts at the foot of the mountains.

38. The leaves of this tree are half-cordate, or ſo on the upper ſide, but half-lanceolate on the hinder ſide, three-nerved with the nerves branching, tomentoſe underneath, glaucous, on the wider ſide ſcarce manifeſtly ſerrate, petioled. In the axils, on the oppoſite ſide are very many ſmall cluſtered flowers, but on the ſame ſide with the petiole behind, a recurved prickle [f].

This is very diſtinct from its congeners by the great obliquity of the leaves, which are almoſt half-cordate, and acuminate [g].—Native of the iſland of Ceylon.

39. Native of the Cape of Good Hope [h].

40. Branches ſimple, oppoſite, ſpreading very much, angular, even. Prickles ſolitary, fixed, horizontal, recurved, ſolid. Leaves by the ſide of the prickles, even, obſoletely toothed, on petioles the

Digitized by Google

length of the prickles. Stipules two, very minute. Fructifications lateral, without prickles, umbelled, a little longer than the petiole's, ſimple. Calyx bell-ſhaped, cut round: border upright, five-parted; with acute deciduous teeth. Petals five inſerted into the calyx, obcordate, ciliate, ſnow-white, involving the anthers. Filaments five, alternate, a little ſhorter than the calyx. Anthers erect, oblong. Germ ſuperior. Style ſhort, permanent. Stigma emarginate. Fruit globular, clothed at the bottom with the baſe of the cut calyx. Seeds three obcordate, compreſſed.

Native of the Eaſt Indies, in buſhy places; where it was firſt obſerved by Koenig[1].

41. Sometimes both prickles are ſtraight, ſometimes the ſhorter one is recurved. Calyx ſtellate, with the ſegments on the upper ſurface plaited through the middle. Petals deeply hollowed like a ſnail's ſhell, upright, but after-flowering bent back. Styles two or three[k]. Drupe berried, ſuperior, ovate-oblong, ſub-umbilicate or obtuſe at both ends, ſmooth, ſcarlet: pulp granular, ſweet: ſhell or ſtone bony, ovate, acuminate at each end, wrinkled with little excavations, having at the baſe a tranſverſe, prominent, compreſſed, acuminate callus, like an incomplete ſuture; two-celled, valveleſs. In each cell is one ſeed, of a rounded-ovate ſhape, flatted a little, plano-convex, ruſeſcent and at the umbilicus blackiſh; faſtened to the bottom of the cell[l].

Thunberg deſcribes the ſtem as ſhrubby and branched; the branches and branchlets filiform and ſmooth; the prickles ſcattered, ſolitary or in pairs, commonly erect; the leaves alternate, on very ſhort petioles, ſcarcely cordate, ovate and ovate-oblong, blunt with a very fine point, ſometimes but ſeldom retuſe, ſerrate, ſmooth, pale underneath, three-nerved, an inch long; flowers axillary, two, three or more together, very ſhort and unequally peduncled; ſtyles two very ſhort, with capitate ſtigmas.

According to Loureiro, it is a middle-ſized tree, with twiſted branches ſpreading a little; and very many long ſtraight ſubſolitary prickles. Leaves oblong-ovate, ſerrate, three-nerved, ſmooth on both ſides. Flowers greeniſh-white, on axillary ſhort peduncles, commonly ſingle. Calyx corolline, wheel-ſhaped, five-cleft. Stamens five, defended by as many ſcales. Stigmas two ſeſſile. Drupe middle-ſized, ovate-oblong, browniſh-yellow, fleſhy; incloſing an oblong two-celled nut.

Desfontaines deſcribes it as a branching tree, with prickles in pairs, one ſtraight, the other curved in and ſhorter; the leaves ſmooth, ſhining, ovate-oblong, ſerrate, three-nerved; on a very ſhort petiole. Flowers paliſh yellow, axillary, ſolitary and aggregate, each on ſhort pedicels: petals alternate with the calycine ſegments, ſmall, bagged. Drupe ſhaped like an olive, ſmooth, when ripe ſaffron-coloured; incloſing an oblong two-celled nucleus.

Pallas has a ſhrub, not uncommon in Georgia, and the Perſian ſide of the Caſpian ſea, which he ſays appears to be the *Rh. Zizyphus* of Linneus, although the younger branches which were ſent him had no prickles on them. According to him, the branches are woody, the thickneſs of a quill, and teſtaceous. From one bud ſpring two or three annual ſhoots, a ſpan long, filiform, ſubpubeſcent, leafed alternately. Leaves on ſhort petioles, ovate-lanceolate, obſcurely ſerrulate, blunt, three-nerved, often unequal at the baſe, ſcarce apparently pubeſcent underneath. Stipules briſtle-ſhaped, ſlender. Flowers hermaphrodite from all the axils, three or four, ſeldom more, forming a ſort of ſubpeduncled corymb, ſmall, five-cleft, greeniſh-yellow, almoſt as in Paliurus. The berries nearly equal the ſize of the drupe in *Cornus ſanguinea*; they are ſolitary in the axils, and peduncled. It is figured under the name of *Rh. paliuroides*.

Native of the South of Europe, China, Cochin-china and Japan. The fruit is ſold in the market at Canton during the autumn.] In Italy and Spain it is ſerved up at the table in deſerts during the winter ſeaſon, as a dry ſweetmeat. [Mr. Ray obſerved plenty of the freſh fruit expoſed to ſale at Venice. He ſaw abundance of the ſhrubs wild in Calabria. The Jujube is ſaid to have been firſt introduced into Italy from Syria by Sextus Pampinius, in the time of Auguſtus: but I ſuppoſe we are to underſtand this of the variety improved by cultivation; as in the introduction of the Cherry by Lucullus. It was cultivated here in 1640, as appears from Parkinſon[m].

Miller has four ſpecies of Zizyphus; the third, which he names *Z. Oenoplia*, does not ſeem to be the *R. Oenoplia*, but the *R. Jujuba* of Linneus: the fourth is the *R. Spina Chriſti*. The two firſt belong to this ſpecies, and are the Jujube in its cultivated and wild ſtate; according to him,]

Zizyphus Jujuba, the common or cultivated Jujube has a woody ſtalk, dividing into many crooked irregular branches, armed with ſtrong ſtraight thorns, ſet by pairs at each joint. The leaves are two inches long and one broad, ſlightly ſerrate, on ſhort foot-ſtalks. The flowers are produced on the ſide of the branches, two or three from the ſame place, ſeſſile, ſmall and yellow. Fruit oval, the ſize of a middling Plum, ſweetiſh and clammy, including a hard oblong ſtone, pointed at both ends.

The Z. ſylveſtris or wild Jujube, grows about Tunis in Africa. It has ſlender woody ſtalks, which ſend out many weak branches, covered with a grayiſh bark, and armed with ſpines in pairs, one longer and ſtraight, the other ſhort and recurved. Leaves ſmall, oval, veined, half an inch in length and breadth, and ſeſſile.

42. This ſends up ſeveral ſhrubby ſtalks, dividing into ſlender branches, armed with ſtraight ſpines, (prickles) ſet by pairs at each joint. Leaves ſmall, ovate, veined, alternate, upon very ſhort foot-ſtalks. Flowers ſmall, yellow, axillary. Fruit round, about the ſize of the Sloe.

[Desfontaines deſcribes it as an upright tree. Leaves alternate, perennial, blunt, notched about the edge, three-nerved, on ſhort petioles: the younger ones pubeſcent underneath. Prickles ſhort; one ſtraight, the other recurved. Drupe oblong, the ſize of a wild Plum, on a ſhort pedicel, incloſing a roundiſh nucleus or ſtone. The fruit is eatable and pleaſant.

In all probability, ſays Haſſelquiſt, this is the tree which afforded the crown of thorns, put on the head of Chriſt. It grows very common in the Eaſt, and was very fit for the purpoſe; for it has many ſmall ſharp ſpines, well adapted to give pain. The crown might be eaſily made of theſe round pliant branches; and what ſeems to be the greateſt proof is, that the leaves much reſemble thoſe of Ivy. Perhaps the enemies of Chriſt would have a plant ſomewhat reſembling that, with which Emperors and Generals were uſed to be crowned, that there might be calumny even in the puniſhment[n].

Native of Ethiopia and Paleſtine: *Lin.*—of Barbary, in woods of dates near Tozzer: *Desfont.*—Egypt: *Alp. and Veſling.*—Linneus raiſed it from ſeeds ſent by Haſſelquiſt. Mr. Miller cultivated it in 1759, from ſeeds.

General Obſervations.

The ſpecies of this genus are all either trees or ſhrubs: which are thorny, prickly, or unarmed; hence a three-fold ſubordinate diviſion of the genus. One ſpecies (volubilis, n. 17.) has a twining ſtem: and one (myſtacinus, n. 26.) climbs by means of tendrils. Some have one upright trunk, but more have ſeveral ſhrubby ſtems, and ſome are decumbent, and even in a manner attached to the ground. The leaves are commonly alternate; but ſometimes almoſt or quite oppoſite; never compound, ſeldom jagged, moſtly entire: frequently (5, 6, 31.) of a firm conſiſtence, ſhining and ever-green. The flowers are axillary, ſmall, and make little appearance, being commonly of a greeniſh yellow or herbaceous colour. The calyx, which Linneus calls the corolla, is five-cleft or five-toothed, in moſt of the ſpecies; but it is four or five-cleft in ſome, as in *Rh. Prinoides*, n. 20.;

[1] Linn. ſuppl. [k] Willich & Scop. [l] Gærtner. [m] Hort. kew. [n] Travels, p. 289. Engl. edit.

three

Digitized by Google

three or four-cleft, with three or four ſtamens in *Rh. ſaxatilis*, *n.* 7.; and four-cleft in ſeveral; as *Rh. catharticus*, *n.* 1. *infectorius*, *n.* 2. *Erythroxylon*, *n.* 4. *crenulatus*, *n.* 6. *dauricus*, *n.* 18. *alpinus*, *n.* 19. The ſtamens ſhould regularly be five, but in *Rh. catharticus* and *infectorius* there are only four, and indeed their number generally correſponds with the diviſions of the calyx. Moſt of the ſpecies have one ſtyle, correſponding with the order in which they are placed by Linneus: but *Rh. Alaternus*, *n.* 31. *Lotus*, *n.* 34. *Napeca*, *n.* 35. *Jujuba*, *n.* 36. and *Zizyphus*, *n.* 41. have two ſtyles, or at leaſt the ſtyle cloven half way. *Rh. Erythroxylon*, *n.* 4. and *Paliurus*, *n.* 33. have three ſtyles; in *ellipticus*, *n.* 24. the ſtyle is three-parted to the very baſe: and in *Prinoides*, *n.* 25. it is ſubtriple. In many ſpecies the ſtyle is cloven at top, or is terminated by two or more ſtigmas. In *Rh. lævigatus*, *n.* 11. and *Frangula*, *n.* 21. the ſtigma is bifid; and in *dauricus*, *n.* 18. twin. In *cubenſis*, *n.* 15. *colubrinus*, *n.* 16. *myſtacinus*, *n.* 26. and *ſphæroſpermus*, *n.* 28. it is trifid. In *Rh. catharticus*, *n.* 1. and *alpinus*, *n.* 19. it is four-cleft. *Rh. infectorius* has two reflexed ſtigmas.—The flowers in moſt of the ſpecies are hermaphrodite; but in ſeveral they are dioecous or polygamous. *Rh. catharticus*, *n.* 1. has male and female flowers on ſeparate individuals; but ſometimes there is a mixture of hermaphrodites, and in Ruſſia, according to Pallas, they are for the moſt part perfect. *Rh. infectorius*, *n.* 2. is ſaid to be dioecous. In *Erythroxylon*, *n.* 4. there are male flowers both on a diſtinct ſhrub and with the females; but female flowers never occur on the male ſhrub. In the *lycioides* of Pallas, which is reputed to be a variety of this, the flowers are always hermaphrodite. The flowers are dioecous in *Rh. crenulatus*, *n.* 6. *dauricus*, *n.* 18. *alpinus*, *n.* 19. In *Prinoides*, *n.* 25. they are ſaid to be polygamous.

The fruit, in the greater part is a Berry, but in ſome it is a Drupe, and this has given occaſion to ſome botaniſts to divide the genus.

Mr. Miller, who followed Tournefort in his former editions, treated theſe plants to the laſt under the ſeveral ſeparate articles of *Alaternus*, *Frangula*, *Paliurus*, *Rhamnus* and *Zizyphus*. Gærtner, who chiefly regards the fruit in his conſtruction of genera, has ſeparated *Paliurus* and *Zizyphus* from *Rhamnus*. Willdenow has made two genera of theſe plants, thoſe which have a berry for a fruit he places under *Rhamnus*; and ſuch as have a drupe, under *Zizyphus*: the latter comprehending, beſides thoſe ſpecies commonly known by that name or that of *Jujube*, the *Paliurus*, *Rhamnus lineatus* and *volubilis*. I have given the genus as Linneus left it; being averſe, as I have already obſerved, from dividing natural genera. If we were to attend here to artificial diſtinctions, or mere differences in the pericarp, we might make almoſt as many genera as there are ſpecies.

The fruit, in the two firſt diviſions is a berry, except in *cubenſis*, *colubrinus* and *ellipticus*, in which it is a three-celled or ſubtricoccous capſule; in *volubilis* and *lineatus*, which have a drupe incloſing a two-celled nut. In *R. catharticus*, *n.* 1. the berry is four-celled, with one ſeed in each cell; in *R. infectorius* one of the four cells is commonly empty; but that happens not unfrequently in the *catharticus*: in *R. oleoides*, *n.* 5. and *lycioides* of Pallas, *n.* 4. β. it is two-celled and two-ſeeded. Other ſpecies have ſometimes only two cells and two ſeeds, as *n.* 21. 31. and *n.* 28. has ſometimes only one ſeed, but this is owing to one or two of the germs proving abortive. In *R. ſaxatilis*, *n.* 7. *pumilus*, *n.* 20. *Frangula*, *n.* 21. *ſphæroſpermus*, *n.* 28. and *Alaternus*, *n.* 31. the natural number of ſeeds is three: but in *Frangula* there are moſt frequently no more than two in a berry; in *ſphæroſpermus* the number varies from one to three: and in *Alaternus* there are often only two; one or two of the germs failing, as is not uncommon in other plants. That the natural number is three, at leaſt in the two laſt, we may fairly infer from the ſtyle being trifid.

The ſpecies of this variable genus do not differ ſo much in the ſtamens as in the ſtyle, the uſual number being five: *R. catharticus* and *infectorius* follow the diviſions of the calyx in having only four ſtamens: as does alſo *R. ſaxatilis*, *n.* 7. in having three or four ſtamens, according as the calyx is trifid or quadrifid.]

PROPAGATION AND CULTURE.

1. The purging Buckthorn ſhrub is ſo common in the hedges of many parts of England, that it is ſeldom cultivated in gardens. It riſes eaſily from ſeeds, if they are ſown in autumn ſoon after the berries are ripe; but if they be kept out of the ground till ſpring, the plants will not come up till the year after. Theſe will require no particular treatment, but may be managed in the ſame way as young Crabs, or any other hardy deciduous tree or ſhrub. It may alſo be propagated by cuttings or layers. If the young ſhoots be layed in autumn, they will put out roots by the following autumn, when they may be taken off, and either planted in a nurſery to get ſtrength for a year or two, or where they are deſigned to remain. This is not ſo proper for hedges as the Hawthorn or Crab.

2. 7. Theſe are chiefly preſerved in botanic gardens; for not being beautiful few perſons cultivate them in England, eſpecially as they do not produce fruit with us. Lay down the young branches in autumn, or plant cuttings in the ſpring, before the buds begin to ſwell. Treat them in the ſame way as the common ſort.

16. Sow the ſeeds upon a hot-bed in the ſpring, and when the plants are fit to remove, put them ſeparately in ſmall pots, filled with light ſandy earth: plunge them into the tan-pit, and ſhade them till they have taken root; then treat them in the ſame manner as other tender exotic plants. In the autumn place them in the bark ſtove, and during the winter water them, but with great caution; for too much moiſture at that ſeaſon will deſtroy them.

21. Sow the ſeeds as ſoon as they are ripe. Keep the plants clean till autumn, and then plant them in a nurſery, in rows two feet aſunder, and at one foot diſtance in the rows. Here let them remain two years, and then plant them where they are to remain. This ſhrub may alſo be increaſed by layers or cuttings; but the ſeedling plants are beſt.

31. The Alaternus is eaſily propagated by laying the branches down, as is practiſed for many other trees. The beſt time for this is in the autumn, and if properly performed, the layers will have made good roots by the autumn following, when they may be cut off from the old ſtock, and planted either into the nurſery, or in the places where they are deſigned to remain. When they are planted in a nurſery, they ſhould not remain there longer than a year or two; for as they ſhoot their roots to a great diſtance on every ſide, ſo they cannot be removed after two or three years growth, without cutting off great part of them, which is very hurtful to the plants, and will greatly retard their growth, if they ſurvive their removal; but they are frequently killed by tranſplanting, when they have ſtood long in a place. They may be tranſplanted either in the autumn or the ſpring, but in dry land the autumn planting is beſt, whereas in moiſt ground the ſpring is to be preferred.

The plain ſorts may alſo be propagated by ſowing their berries, which they produce in great plenty, but the birds are greedy devourers of them; ſo that unleſs the berries are guarded from them, they will ſoon be devoured when they begin to ripen. The plants which ariſe from ſeeds, always grow more erect than thoſe which are propagated by layers, ſo are fitter for large plantations, as they may be trained up to ſtems, and formed more like trees: whereas the layers are apt to extend their lower branches, which retards their upright growth, and renders them more like ſhrubs. They will grow to the height of eighteen or twenty feet, if their upright ſhoots are encouraged; but to keep their heads from being broken by wind or ſnow, thoſe branches which ſhoot irregular ſhould be ſhortened, which will cauſe their heads to be cloſer, and not in ſo much danger.

All the varieties thrive beſt in a dry, gravelly, or ſandy ſoil, for in rich ground they are often injured by froſt, when the winters are ſevere, but in rocky dry land they are ſeldom injured: and if in very hard froſt

Digitized by Google

froſt their leaves are killed, yet the branches will remain unhurt, and will put out new leaves in the ſpring.

33. Procure the ſeeds from ſome of the ſouthern countries of Europe, for they do not ripen in England.

Theſe ſeeds ſhould be ſown as ſoon as poſſible after they arrive, on a bed of light earth, and the plants will come up the following ſpring; but when the ſeeds are kept out of the ground till ſpring, they will not come up till the next year, and very often fail; therefore it is much the beſt way to ſow them in the autumn. Theſe ſeedling plants may be tranſplanted the following ſeaſon into a nurſery to get ſtrength, before they are planted out for good.

It may alſo be propagated by laying down its tender branches in the ſpring of the year, which if carefully ſupplied with water in dry weather, will take root in a year's time, and may then be taken off from the old plant, and tranſplanted where they are to remain.

The beſt time for tranſplanting this plant is in autumn, ſoon after the leaves decay, or the beginning of april, juſt before it begins to ſhoot, obſerving to lay ſome mulch upon the ground about their roots to prevent them from drying, as alſo to refreſh them now and then with a little water until they have taken freſh root, after which they will require but very little care. They are very hardy, and will grow to be ten or twelve feet high, if planted in a dry ſoil and a warm ſituation. There is little beauty in this plant, but it is kept in gardens as a curioſity.

36 to 38. 41. 42. Theſe plants are preſerved in the gardens of ſome curious perſons only for the ſake of variety, for they do not produce fruit in England. The 41ſt and 42d ſorts, which are the moſt hardy, will ſcarcely live through the winters in England, even when they are planted againſt ſouth walls; in which ſituation I have kept the plants two or three years, when the winters have proved mild, but they were afterwards killed by a ſharp froſt. They may be propagated by putting their ſtones into pots of freſh light earth, ſoon after their fruits are ripe; and in winter they ſhould be placed under a common hot-bed frame, where they may be ſheltered from ſevere froſt. In the ſpring theſe pots ſhould be plunged into a moderate hot-bed, which will greatly forward the growth of the ſeeds; and when the plants are come up, they ſhould be inured to the open air by degrees, into which they muſt be removed in june, placing them near the ſhelter of a hedge; and in very dry weather they muſt be frequently refreſhed with water.

In this ſituation they may remain till the beginning of october, when they muſt be removed into the greenhouſe, or placed under a hot-bed frame, where they may be defended from froſt, but ſhould have as much free air as poſſible in mild weather.

During the winter ſeaſon they ſhould be now and then refreſhed with water; but after their leaves are fallen (as they always ſhed them in winter), they muſt not be over watered, which would rot the tender fibres of their roots, and cauſe the plants to decay.

In march, juſt before the plants begin to ſhoot, they ſhould be tranſplanted, each into a ſeparate ſmall pot filled with light freſh earth; and if they are plunged into a moderate hot-bed, it will greatly promote their taking root; but in may they muſt be inured to the open air by degrees, into which they ſhould be ſoon after removed.

Thus theſe plants ſhould be managed while young, at which time they are tender; but when they are three or four years old, ſome of them may be planted in the full ground, againſt a warm wall or pale, where, if they have a dry ſoil, they will endure the cold of our ordinary winters pretty well; but in hard froſts they will require to be ſheltered, ſo it will be proper to keep a plant or two in pots, which may be houſed in winter.

DESCRIPTIONS, *&c.*

1. This has a large thick root, which divides into many ſtrong fleſhy fangs, running deep in the ground; the outſide is of a reddiſh brown colour, and the inſide yellow, from which ariſe ſeveral leaves, in number according to the ſize of the root; theſe come up folded in the ſpring, and afterward expand themſelves; they are ſmooth, of a roundiſh heart-ſhape, having very thick foot-ſtalks of a reddiſh colour, which are a little channelled on their lower part, but flat at the top. When the plant grows in rich land, the foot-ſtalks of the leaves are near two feet long, and thicker than a man's thumb; the leaves alſo are often two feet long, and as much in breadth, having ſeveral ſtrong longitudinal veins running from the foot-ſtalk to the borders, of a deep green, and waved on their edges, having an acid taſte, but particularly the foot-ſtalks, which are now frequently uſed for making tarts. From between the leaves ariſes the flower-ſtem, which is of a purple colour, garniſhed with one leaf at each joint, of the ſame ſhape with thoſe below, but ſmaller, and ſitting cloſe to the ſtalk. The ſtalks grow from two to three feet high, according to the ſtrength of the ground, and are terminated by thick, cloſe, obtuſe ſpikes of white flowers, which appear the beginning of june, and are ſucceeded by large, triangular, brown ſeeds, having a border or wing at each angle; they ripen in auguſt.

When the ſeeds were firſt brought to Europe, they were ſuppoſed to be thoſe of the true Rhubarb; but upon making trial of the roots, they were found to be greatly inferior to thoſe of the true Rhubarb; and upon farther examination, it was diſcovered to be the *Rhaponticum* of Proſper Alpinus.

[Native of Aſia. It was cultivated in 1629, by Mr. John Parkinſon[r]; who informs us, that it was ſent him from beyond ſea by a worthy gentleman Dr. Matth. Liſter, one of the King's phyſicians; and firſt grew with him, before it was ever ſeen or known elſewhere in England[s].]

2. The ſeeds of the ſecond ſort were ſent me from Leyden by the late Dr. Boerhaave, by the title of Rhabarbarum Chinenſe verum, or true China Rhubarb, and ſucceeded in the Chelſea garden. The root of this ſort divides into a number of thick fibres, which run deeper into the ground than thoſe of the firſt, and are of a deeper yellow within. The leaves appear much earlier in the ſpring; the foot-ſtalks are not ſo much channelled on their under ſide, and are plain on their upper, not ſo red nor ſo thick as thoſe. The leaves are longer, running more to a point, and are much waved on their edges, a little hairy on their upper ſide, and have many ſtrong veins or ribs on their under. The flower-ſtem is of a pale browniſh colour, riſing about four feet high, dividing into ſeveral looſe panicles or bunches of white flowers, which appear in may, and are ſucceeded by triangular ſeeds like thoſe of the firſt ſort, which ripen earlier in the ſeaſon.

[Seed ovate-pyramidal, three-ſided, the ſides obſcurely ſtriated, and of a ferruginous brown colour; wings of the angles narrow, waved, ruſeſcent-yellow. Albumen farinoſe, deeply grooved, widely deficient at the place of the radicle[t].

Native of China and Siberia. Cultivated in 1759, by Mr. Miller[u].

3. Root perennial, (as all the other ſpecies are) thick, of an oval ſhape, and ſends off long tapering branches; externally it is brown, internally of a deep yellow colour. Stem erect, round, hollow, jointed, ſheathed, ſlightly ſcored, branched towards the top, from ſix to eight feet high. Root-leaves numerous,

[r] Hort. kew. [s] Parad. 484. [t] Gærtner. [u] Hort. kew.

large,

Digitized by Google

large, rough, of a roundiſh figure, deeply cut into lobes and irregularly pointed ſegments; on long ſmooth round footſtalks. Stem-leaves one at each joint, from a membranous ſheath, ſucceſſively ſmaller upwards. Flowers ſurrounding the branches in numerous cluſters, and forming a kind of ſpike. Corolla of a greeniſh white colour[x].

Seed ovate-elliptic, emarginate at the top and baſe, three-ſided; the ſides wrinkled and ſomewhat ſcrobiculate; the angles winged, membranaceous ſmooth. Integument double, membranaceous: the outer bay, widened into the wings; the inner of a deep rufeſcent colour, faſtened to the albumen. Albumen ovate-pyramidal, three-ſided, ſhorter than the embryo, or deficient at the place of the radicle, farinoſe, two-parted, ſnow-white. Embryo inverted, ſtraight, central, white. Cotyledons ovate-oblong, ſlightly concave. Radicle awl-ſhaped, extended beyond the albumen, ſuperior[y].

This ſpecies cannot be miſtaken, if we attend to its ſuperior height, the ferruginous or reddiſh brown colour of the ſtem branches and petioles, the particular palmate form of the leaves, and the elegant looſeneſs of the little panicles of flowers. Linneus adds, that the vernal bud is not red but yellow; and that the leaves are ſomewhat rugged; and that the ſegments of the leaves are oblong and ſharpiſh.

Native of China and Tartary. Cultivated before 1768, by Mr. Miller[z].] In the laſt folio edition of the Dictionary, which was publiſhed in that year, he ſays that the ſeeds had been then lately brought to England, from which many plants were raiſed; but that the plant in the Chelſea garden had not flowered, nor had he ſeen any plants in that ſtate. [It flowers in april and may.

The Rhaponticum (n. 1.) is ſuppoſed to be the Ῥῆον, Rheum or Rha of Dioſcorides and the ancients. It was long ſuppoſed to be the true Rhubarb, till the diſcovery of the *undulatum*, when that was taken to be the true Rhubarb. In the year 1724, Profeſſor Bradley ſays, (in his Huſbandry and Gardening, vol. 3. 2. p. 64.) I could wiſh that we could get ſome of the true Rhubarb, if poſſible, for this has not yet grown in Europe, as I could ever find; though once, I remember, the late ingenious Mr. Jacob Bobart thought he had got it.

It was not until the year 1732, that botaniſts became acquainted with any ſpecies of Rheum, which ſeemed to afford the officinal Rhubarb, when ſome plants received from Ruſſia by Juſſieu at Paris and Rand at Chelſea, were ſaid to ſupply this important deſideratum, and as ſuch were adopted by Linneus, in his firſt edition of the Species Plantarum, under the name of *Rheum Rhabarbarum*. (Mr. Miller had the ſeeds from Boerhaave in 1734.)

This however was not very generally received as the true Rhubarb; and with a view to aſcertain this matter more completely, Boerhaave procured from a Tartarian Rhubarb merchant the ſeeds of the plants which produced the roots that he annually ſold, and were admitted at St. Peterſburgh to be the genuine Rhubarb. Theſe ſeeds were ſoon propagated and were diſcovered by De Gorter to produce two diſtinct ſpecies, namely, the *Rhabarbarum* of Linneus, or as it has ſince been called, *undulatum*; and another, a ſpecimen of which being preſented to Linneus, he declared it to be a new one, and introduced it in his ſecond edition of the Species Plantarum by the name of *Rheum palmatum*. Previous to this, De Gorter had repeatedly ſent the ſeeds to Linneus, but the young plants which they produced conſtantly periſhed; at length he obtained the freſh root, which ſucceeded very well at Upſal, and afterwards enabled the younger Linneus to deſcribe this plant in the year 1767. But two years antecedent to this, Dr. Hope's account of the *Rheum palmatum*, as it grew in the botanic garden near Edinburgh, had been read before the Royal Society in London. The ſeeds were firſt introduced into Britain in 1762, by Dr. Mounſey, who ſent them from Ruſſia[a]; and theſe ſeeds were quickly diſperſed over the iſland. At the ſame time that Dr. Hope cultivated them at Edinburgh, I raiſed abundance of the plants in the botanic garden at Cambridge, from Dr. Mounſey's ſeeds, which all produced the *R. palmatum*; and I have ſome of the Dr.'s original pacquet ſtill by me. No doubt Mr. Miller's plants were raiſed from the ſeeds ſent by Dr. Mounſey, though he does not mention his name. It appears that the ſeeds ſent from St. Peterſburgh to this country uniformly and conſtantly produced the *R. palmatum*, and not ſometimes *R. undulatum* alſo, as De Gorter relates the ſeeds to have done, which Boerhaave obtained from the Tartarian merchant. This however does not prove, that other ſpecies, as the *undulatum* and *compactum*, do not yield the true Rhubarb, as well as the *palmatum*. We have ſeen that the *undulatum* was ſent from Tartary with the *palmatum*, for the genuine plant; and Georgi relates that a Coſſack pointed out the ſame ſpecies to him, for the true Rhubarb. Both he and Pallas remark, that poſſibly the root of *R. undulatum* may be better on the more ſouthern open and dry mountains of Tibet, than on the colder wet mountains of Siberia. Profeſſor Pallas relates that in Bukharia, the *R. palmatum* ſeems to be unknown, and that as far as he could collect from deſcription, the ſpecies they conſider there as the true one is the *compactum*; the ſeeds of which, Mr. Miller informs us, were ſent to him from St. Peterſburgh as the true Tartarian Rhubarb.—*See the account of the next ſpecies.*

For many years I have been of opinion that the true Rhubarb root is taken from ſeveral ſpecies, and the foregoing account confirms this ſuppoſition.

Dr. Lettſom, in the year 1778, ſays there is every reaſon to conclude that *Rheum palmatum* is the Turkey or Ruſſia Rhubarb.

Dr. Pulteney, in the year 1783, remarks that Pallas ſeems to have determined the Ruſſia Rhubarb to be the *R. palmatum*; and that the Chineſe Rhubarb is the *R. undulatum*. He farther mentions his having been informed that theſe two ſpecies, planted near each other, will produce a mongrel plant; and ſuggeſts that the root of the latter may poſſibly excel that of the parent plants. See *R. hybridum*.

Dr. Hope ſays, in 1784, that the Rhubarb which we receive through Ruſſia, formerly called Turkey Rhubarb, is the root of the *palmatum*, and different from that which is received from China.

The Society for the Encouragement of Arts, Manufactures, and Commerce, has exerted itſelf for many years, in promoting the cultivation of the *Rheum palmatum* in Great Britain, and apparently with much ſucceſs.

Sir Alexander Dick had the Gold Medal of the Society, for a memoir on the culture and drying of it. Sir William Fordyce, ſo early as the year 1780, took up three roots, ſix years old, weighing when waſhed, ten pounds ſix ounces avoirdupois. He ſtripped off the bark from the ſmaller roots, and cut off moſt of it from the larger parts; and hung them up in feſtoons on packthread, three or four inches from each other, at a moderate diſtance from the fire. From theſe roots he had one pound four ounces of Rhubarb, as fit for the market as any imported from Ruſſia, Turkey, or China: he obtained likewiſe, one pound more, fit for private uſe, or to be powdered. The roots ſhould be cleared entirely of the rind; for the parts which are covered with it, will be apt to turn mouldy. Large pieces ſhould have a perforation made through the middle, that they may dry more perfectly, with leſs fuel and in leſs time.

At the end of ſix or ſeven years, when the plant ſeems to arrive at its moſt perfect ſtate, one pound of Rhubarb may be obtained from every five pounds of the green roots; beſides an equal or larger proportion of roots fit for family uſe, or powder in the ſhops[b].

In 1791, the gold medal of the Society was given to this gentleman, for raiſing above three hundred plants of the true Rhubarb from ſeed, and tranſplanting them at four feet diſtance[c].

ſowed

Digitized by Google

ſowed ſixty ſeeds, being part of thoſe which were ſent to the Society by Dr. Mounſey in 1764; and they produced forty-five plants. In 1784 he raiſed upwards of a hundred and twenty plants in the common ground, from ſeeds of the preceding year. He had ſent to the Society two roots, weighing twenty-eight and thirty pounds: but this year he ſent a ſingle root, which weighed, when taken up on the ſixteenth of october fifty-ſix pounds; in a few days it loſt four or five pounds, and on the eighth of november, when it was weighed before a Committee, it was found to weigh only forty-eight pounds. The largeſt root before produced to the Society by Sir Alexander Dick weighed forty-two pounds.

Mr. Robert Davis the younger, of Minehead in Somerſetſhire, merchant, in the ſpring of the year 1779, ſowed ſome ſeed of *R. palmatum*, which he received from Dr. Brockleſby; and planted out ſeven hundred and twenty of the plants, at the diſtance of five feet. The ſoil for the moſt part was ſandy and light, the reſt a deep black loamy garden ground. A great number of plants on the firſt ſoil died; but thoſe on the latter continued for the moſt part vigorous, and produced larger roots than the other, although not ſuperior, if equal in quality. It did not appear that the diſtance of five feet in any reſpect incommoded or injured the moſt luxuriant plants.

In the ſummer of 1783, the whole plantation was taken up, and the number of roots was near, if not quite four hundred. The whole produced three hundred pounds of dried Rhubarb[d].

The gold medal of the Society was adjudged to Mr. John Ball, ſurgeon at Williton, in the pariſh of St. Decuman's, and county of Somerſet, for raiſing in 1788 upwards of four hundred plants of *R. palmatum*, ſtanding ſix feet aſunder each way.

The following year, having by the ſeverity of the winter loſt fifty of the four hundred and thirty plants abovementioned, he filled up the vacancies with young plants, and planted upwards of ſix hundred more at ſix feet apart, and about two hundred at four feet. For this additional plantation he received another gold medal.

It appears that ſome of Mr. Ball's roots, of five years old weighed, when freſh, upwards of ſeventy pounds; and that he uſed the bark for tinctures, finding it full as good in every reſpect, as the beſt part of the root. His practice is to manure or dreſs them with rotten dung, coal aſhes, lime, earth, old mud wall, &c.[e]

In 1792 Mr. Thomas Jones, of Fiſh-ſtreet-hill, London, planted four hundred and twenty plants of *Rheum palmatum*, at ſix feet diſtance; at Four-tree-hill, Enfield, Middleſex, and had the gold medal adjudged to him by the Society.

The ſame year Mr. Halley of Pontefract in Yorkſhire had the Silver medal for producing ſamples of Rhubarb better cured than any that had been produced before. It ſeems that his father had been in the habit of raiſing large quantities of the roots, which in war time he diſpoſed of very freely; but in time of peace the druggiſts procured it from abroad at a lower rate[f].

In 1793, the gold medal was adjudged to Mr. William Hayward, of Banbury, in Oxfordſhire, for raiſing full eight hundred plants of the true Rhubarb: and a third gold medal to Mr. Ball, for poſſeſſing a hundred and fifty eight pounds of it, of his own growth and curing, equal in quality to Turkey or Ruſſia Rhubarb; and communicating his culture of it[g].

The year following, Mr. Ball had a fourth gold medal adjudged to him for poſſeſſing ninety-ſeven pounds of the true Rhubarb of his own growth; and for communicating the culture and method of cure[h].

In 1795, Mr. Robert Davis beforementioned, of Minehead in Somerſetſhire, had the gold medal, for raiſing nine hundred and thirteen Rhubarb plants, and giving ſome account of their culture. Alſo the ſilver medal to Nicholas Aſhton, of Woolton Hall, near Liverpool, Eſq. for ſending ſamples of Rhubarb very well cured. This Rhubarb was planted in 1778 or 1779; and was taken up and cured in october 1795[i].

In 1797, the gold medal was adjudged to the Rev. James Stillingfleet, of Hotham in Yorkſhire, for his culture and cure of Rhubarb, of which he gives an ample detail. Alſo to Mr. Thomas Jones beforementioned, for raiſing nine hundred and thirty-five plants, and giving a full account of his method of culture[k].

The following year, the ſame Mr. Jones had a reward of thirty guineas from the Society, for having raiſed and planted three thouſand and forty plants of the true Rhubarb; making up the whole number raiſed by him nearly five thouſand, ſince the year 1792. He here adds many excellent hints reſpecting its culture[l].

This account may ſerve to ſhow, both the ardour of our reſpectable Society in encouraging the growth of this uſeful article, and the perſevering induſtry of ſome gentlemen, in overcoming all the difficulties attendant on introducing a new plant into cultivation, finding out the means of curing it as an article for extenſive ſale, and overcoming the prejudices of ſuch as cannot perſuade themſelves that a drug of Britiſh growth can bear a competition with what is ſent us from foreign countries.

The growth of the *R. palmatum* is remarkably quick. A plant ſix years old grew, between the month of april, when the ſtalk firſt emerged out of the ground, and the middle of july, when it was at the greateſt height, to eleven feet four inches. It grew in one day three inches, and in one night above four. Many of the leaves were above five feet long. The root, taken up in october, weighed thirty-ſix pounds, when clean waſhed, and deprived of its ſmall fibres[m].

Medical uſe of Rhubarb.

Rhubarb is cultivated in China, particularly in the province of Xen-ſi, where it is called *Tai-ho-hang*. It comes over to us in oblong pieces, flattiſh on one ſide, and convex on the other; compact, hard, heavy, internally of a dull red colour, variegated with yellow and white, and when recently powdered appears yellow, but on being kept becomes gradually redder.

It is alſo cultivated in the Ruſſian dominions. The beſt is ſaid, by Bell, to grow in a long chain of mountains in Tartary, which extend from Selin to the lake Koko-nor near Tibet. This is commonly called Turkey Rhubarb, becauſe it formerly came to us through Turkey. But it may be more properly named Ruſſian or Tartarian Rhubarb. It is more valuable than the other, and is brought to us in roundiſh pieces, with a large hole through the middle of each; it is more ſoft and friable than the Chineſe, and exhibits, when broken, many ſtreaks of a bright-red colour. The marks of the goodneſs of Rhubarb are, the livelineſs of its colour when cut; its being firm and ſolid, but not flinty or hard; its being eaſily pulverable, and appearing when powdered of a fine bright yellow colour; its imparting to the ſpittle, on being chewed, a deep ſaffron tinge, and not proving ſlimy or mucilaginous in the mouth: its taſte is ſubacrid, bitteriſh, and ſomewhat ſtyptic; the ſmell lightly aromatic.

The purgative qualities of Rhubarb are extracted more perfectly by water than by ſpirit: the root remaining after the action of water is almoſt if not wholly inactive; whereas after repeated digeſtion in ſpirit, it proves ſtill very conſiderably purgative. The quality of the watery infuſion, on being inſpiſſated by a gentle heat, is ſo much diminiſhed, that a dram of the extract is ſaid to have ſcarcely more effect than a ſcruple of the root in ſubſtance: the ſpirituous tincture loſes leſs; half a dram of this extract proving moderately purgative.

The purgative quality of this root is ſo gentle, that it is often inconvenient by reaſon of the bulk of the doſe required, which in adults muſt be from half a

Digitized by Google

dram to a whole one. When given in a large doſe it will occaſion ſome griping, as other purgatives do; but it is hardly ever heating to the ſyſtem, or ſhows the other effects of more draſtic purges. This purgative quality is accompanied with a bitterneſs, which is often uſeful in reſtoring the tone of the ſtomach; and for the moſt part this bitterneſs makes it ſit better on the ſtomach than many other purgatives. Its operation joins well with neutral laxatives; and both together operate in a leſs doſe than either of them would do ſingly.

Some degree of ſtipticity is always evident in this medicine, and as this quality acts when that of the purgative has ceaſed; in caſes of diarrhæa, when any evacuation is proper, Rhubarb has been conſidered as the moſt proper means to be employed. The uſe of Rhubarb in ſubſtance for keeping the belly regular is by no means proper, the aſtringent quality undoing what the purgative had done; unleſs the Rhubarb be chewed in the mouth, and no more ſwallowed than what the ſaliva has diſſolved. Analogous to this, is the uſe of Rhubarb in a ſolution: for in that the aſtringent quality is not ſo largely extracted as to operate with a power equal to that when the Rhubarb is employed in ſubſtance.

The officinal preparations of this drug are, a watery and vinous infuſion, a ſimple and compound tincture. It is alſo an ingredient in different compoſitions, as *Elixir ex aloe & rheo, pilulæ ſtomachicæ, &c.*[a]

Since the true Ruſſia Rhubarb was introduced by Dr. Mounſey in the year 1762 or ſoon after, and was cultivated by Sir Alexander Dick and Dr. Hope of Edinburgh, with a view to bring it into uſe as a medicine, it has been a queſtion whether the root could attain the ſame qualities in our climate, that it has where it is a native. That Britain is not too cold for it, appears clearly from the ſucceſs with which it has been cultivated in Scotland; if it meets with any difficulty here, it muſt be from the moiſture of our climate, and there can be no doubt but that a dry ſoil ſhould be choſen for it. The chief obſtruction to giving the root here a quality equal to foreign Rhubarb, appears to be the difficulty of curing it properly, but this is in a great meaſure got over, and no doubt will be fully conquered by farther experience, if encouragement ſhould be given to the more extenſive cultivation of this moſt uſeful plant at home.

And ſurely Rhubarb merits ſome encouragement, if it be true that not leſs than 200,000l. is paid annually for what is imported into this country. Eſpecially if we conſider the difficulty there may be of procuring this article from Ruſſia, the inferiority of the Chineſe Rhubarb, and the adulterations that are practiſed to render the foreign drug fair to the eye. There remains only to convince our countrymen, that Britiſh Rhubarb is equal to the foreign; or if it be a little inferior, that inferiority is owing merely to a want of ſkill in curing it, which ſkill will ſoon be attained by experience.

The late excellent Dr. Hope, who with Sir Alexander Dick was indefatigable in cultivating the *Rheum palmatum* for medical uſe, relates in the year 1784, that moſt of the apothecaries in Edinburgh uſed no other than what is raiſed in Scotland; that for ſeveral years there has been no other uſed in the Royal Infirmary; and that when a ſound root is well dried, and properly dreſſed, it is in no reſpect inferior to what comes from Ruſſia.

Dr. Lettſom, in the ſame year, having tried Britiſh Rhubarb on himſelf and about forty children concludes, that the exotic plant poſſeſſes no one quality which the other does not contain; that the foreign ſeems to be rather more active, perhaps in the proportion of one third at the utmoſt; and that its ſuperior activity may depend on circumſtances of ſoil, time of taking up the roots, their age, and the methods of drying, which future enquiries may doubtleſs determine.

The Dr. adds, that he ſuſpects young plants to have more mucilage, and leſs of an active reſin than old ones; but that his obſervation does not warrant him to decide what is the propereſt age to take up the roots for medicinal uſe.

Specimens of Engliſh Rhubarb underwent a ſevere trial at Bath by three eminent phyſicians there, Drs. Falconer, Parry and A. Fothergill.

Dr. Falconer reports, that the two ſpecimens of Engliſh Rhubarb anſwer in external marks to the characters of the drug when good; that they are rather inferior in delicacy of taſte to Turkey Rhubarb, but ſuperior in ſome reſpects to the Eaſt-Indian; that perhaps they might have reſembled the Turkey ſtill more nearly, had they been dug up as long a time, and a careful ſelection of the beſt pieces had been made. The red colour is ſaid to be improved by keeping; and Linneus adviſes it to be kept ten years before it is uſed. Vogel relates, that an apothecary is ſent with the Ruſſian caravan that goes to the borders of China to purchaſe Rhubarb, to whom all the Rhubarb is delivered, and he is ſtrictly ordered to ſelect carefully the beſt pieces only, and to burn all the decayed and bad. Upon the return of the caravan to Moſcow or Peterſburgh, it is again put into the hands of perſons ſkilled in pharmacy, who have the care of its being properly dreſſed, and of none but the true ſort being admitted: ſo that after all theſe cautions, none but the choiceſt and faireſt pieces can be exported. If then ſuch a ſelection were made here, and it were kept a due time, the Britiſh Rhubarb might probably equal any of the foreign: eſpecially if other circumſtances were attended to, which will be mentioned, when we come to the culture and curing of it.

From the experiments made on the Engliſh and foreign Rhubarbs it appears, that they are nearly ſimilar as to the parts which water is capable of diſſolving; but that the Turkey appears to contain the largeſt proportion of matter ſoluble in water, and to retain moſt of an aromatic flavour.—That of gum or mucilage, one parcel of Engliſh Rhubarb contained the moſt, and the Eaſt-Indian the leaſt. The other parcel of Engliſh and the Turkey were nearly alike.—That the foreign Rhubarbs are more abundant in reſin, and contain a larger proportion of active ſoluble matter when digeſted in brandy.—That the Turkey poſſeſſes the largeſt quantity of the colouring ingredient, and the Eaſt-Indian moſt of what is ſoluble in rectified ſpirit.—That the Eaſt-Indian poſſeſſed the moſt aſtringency in the watery infuſion; one parcel of the Engliſh and the Turkey were nearly alike in this reſpect, and the other parcel of Engliſh was the weakeſt. In the ſpirituous tincture, the Turkey was the ſtrongeſt, next the Eaſt-Indian, and the Engliſh the weakeſt.

The experiments tried at the Bath hoſpital ſhow that the purgative qualities of the Engliſh ſpecimens are ſcarcely ſo ſtrong as thoſe of the Turkey or even the Eaſt-Indian, but the difference is not great. Some think, that about three parts of the Turkey or four of the Eaſt-Indian, operate as much as five of the Engliſh Rhubarb; but others think the difference is ſcarcely ſo great. In point of aſtringency the Engliſh Rhubarbs do not perceptibly differ from the foreign.

Upon the whole, if Engliſh Rhubarb ſhould be allowed to be inferior to the foreign, which is perhaps doubtful, it appears probable that this inferiority is owing only to ſuch circumſtances as are in the power of attention and induſtry to obviate; and that this might be done in a great meaſure by attending to the age of the plant when taken up; to the root being cut tranſverſely, raſped on the outſide, having the ſappy parts cut out, and being dried quickly; and to its being kept ſome time before it be uſed.

From a great number of trials made by Dr. Parry it appears, that one of the ſpecimens of Engliſh Rhubarb was fully equal in its purgative quality to the Turkey.

Dr. A. Fothergill remarks, that the Turkey, Ruſſian, and even the Eaſt-Indian Rhubarb, being more ſightly to the eye, are more marketable than the Engliſh; but that much artifice is uſed to render them ſuch. It therefore behoves the faculty to examine whether Rhubarb may not acquire ſome noxious qua-

[a] Woodville, Cullen, mat. med.

Digitized by Google

lity from a colouring ſubſtance employed, and whether the griping effects ſo frequently complained of, may not ſometimes proceed from the Dutch yellow, extracted from Buckthorn berries, with which the root is commonly coloured.

The foreign Rhubarb may acquire ſome advantage from ſoil, climate, culture and the mode of drying; but much more probably from its ſuperior age. Bergius ſays, it is not taken up till it is eleven or twelve years old. The tincture of the Turkey Rhubarb taſted rather more aromatic than the reſt, and ſeemed to poſſeſs a ſomewhat higher degree of aſtringency than the Eaſt-Indian, which rather exceeded the tinctures made with the Engliſh ſpecimens, in the ſame quality. From one experiment it appears, that the Eaſt-Indian is a weaker purgative than any of the reſt; and yet this is the drug which is moſt commonly uſed in the ſhops, for making the tincture. Two experiments prove that the Engliſh Rhubarb poſſeſſes the purgative power in a ſuperior degree. From one experiment it appears, that forty-five grains of Turkey Rhubarb contain the purgative quality, nearly equal to ſixty of the Engliſh; that is, the latter requires to be given to the amount of one fourth more, to produce the ſame effect. This coincides with the reſult of trials made ſome years ago; but later experiments evince, that it approaches nearer to foreign Rhubarb in proportion to its age. On the whole, there ſeems much reaſon to believe, that in proceſs of time, we may be enabled not only to ſupply a ſufficient quantity of the genuine drug properly cured for home conſumption, but alſo for foreign markets [o].

About the year 1783, Mr. Ball, of Williton, already mentioned ſold eighty pounds of Rhubarb, of his own raiſing, to a druggiſt in Briſtol, for ſix ſhillings a pound; uſed no other ſort in his ſhop, and always found it to anſwer in every reſpect. He alſo uſed the bark for tinctures, and found it full as good, for that purpoſe, as the beſt part of the root. He is ſatisfied that we grow Rhubarb equal to the Turkey, but have not yet been able to cure it to that perfection [p].

Mr. James Stillingfleet, of Hotham in Yorkſhire, in 1796 relates, that for fifteen years and upwards he has uſed the Engliſh Rhubarb, as a conſtant phyſic for the poor of his pariſh and neighbourhood, and never found it to fail of its proper effects, eſpecially if a teaſpoonful of Magneſia alba be added to each doſe of twenty or twenty-five grains [q].

Mr. Jones, of Fiſh-ſtreet hill, before mentioned, who has cultivated Engliſh Rhubarb with great ſpirit at Enfield, is of opinion that the prevailing prejudice for foreign commodities is of infinitely more conſequence than any obſtacle that can impede its general cultivation. But if the cultivator will endeavour as much as poſſible to give his root the appearance of the foreign, and be moderate in his price, there can be little danger of its riſing in the public eſtimation. All accounts agree, that Britiſh Rhubarb, at ſix or ſeven years growth, properly cured will poſſeſs all the virtues the moſt ſanguine can deſire.

At the inſtigation of Alexander Champion, Eſq. one of the governors, Mr. Jones ſent ſeveral pounds of Britiſh Rhubarb to Guy's hoſpital; and at an interview with the phyſicians, preſented them other improved ſpecimens. They were unanimous in their approbation of them, and gave Mr. Jones an order for as much as he could produce [r].

Theſe accounts may ſuffice to give us hopes of Britiſh Rhubarb ſuperſeding the neceſſity of importing this drug from abroad; a conſideration of no ſmall importance at all times, but eſpecially when the ports of Ruſſia are ſhut againſt us, and not only our merchant ſhips detained contrary to the faith of treaties, but our ſailors driven up into the country and made priſoners in time of profound peace with that power.

If it be objected that we muſt wait at leaſt four years, or as ſome think ſix or ſeven, before the roots will be fit for uſe; it may not be amiſs to obſerve that it may be adminiſtered with ſucceſs when younger in its freſh ſtate, that is undried: by bruiſing half an ounce of the root, and boiling it in half a pint of water, till it is reduced to one quarter of a pint. This has effects ſimilar to the true ſhop Rhubarb [s]. The Tartars are ſaid to hold the recent root in high eſtimation [t]. Dr. Hope remarks, that the ſucculent root is more purgative than the dried, and therefore the more recent it is the better [u].

The root may probably be uſeful, not only as a medicine, but a dye, as may appear from the following trial. Infuſe a portion of the root in water, and to the infuſion, when ſtrained, add a few grains of ſalt of tartar: this will produce a very beautiful red tincture, ſuch as would be valuable for the purpoſes of dyeing a colour, which at this time (1778) is ſo very expenſive; and which, by this means, may probably be amply provided for by the uſe of this root, when it is more generally cultivated [x].

Not only the root, but other parts of the plant are uſeful. Monſ. Thouin, ſuperintendant of the exotic plants at Verſailles, informs us that the recent ſtem is converted into a marmalade, which is conſidered as a mild and pleaſant laxative, and highly ſalubrious.

They prepare it by ſtripping off the bark, and boiling the pulp with an equal quantity of honey or ſugar. The leaves are employed in their ſoups, to which they impart an agreeable acidity, like that of Sorrel.

The ſeeds have the ſame medicinal property with the root, in an eminent degree [y]. The late Dean of Gloceſter, Dr. Tucker, having dropped a hint of this to Dr. A. Fothergill of Bath, he determined to try them. From his trials it appears that twelve grains of the ſeeds operate on ſome perſons nearly as much as twenty on others, of the ſame age. On ſome they act gently, on others more roughly, ſuch is the difference of conſtitution. In general it appears that twenty grains of the ſeeds are equal to thirty of the root, as to the purgative power. That the reſiduum of the ſeeds is nearly equal in this reſpect to their powder, according to what has been diſcovered concerning the reſiduum of the root; but the proof ſpirit extracted leſs from the ſeeds, than from the root by way of tincture. That the ſeeds appear to be more aromatic than the root, but to contain leſs aſtringency than even its reſiduum, when treated in the ſame manner [z].

A ſelenitic ſalt has been lately diſcovered to be a conſtituent principle in Rhubarb, among other aſtringent vegetables. Sheele pronounces it to be a combination of the acid of wood-ſorrel with a calcarious earth [a].

Some writers affirm, that the diſtilled water of Rhubarb contains a purgative quality, but this ſtands in need of confirmation. The chemical and medicinal properties of the reſiduum; the elaſtic fluid extricated by diſtillation; the eſſential ſalt juſt mentioned, and the aſtringent principle, may all deſerve the attention of a curious obſerver, and perhaps throw new light on the qualities of this important drug [b].]

4. The ſeeds of the fourth ſort were ſent me from Peterſburgh, for the true Tartarian Rhubarb. The roots are large, and divide into many fangs; they are yellow within; the leaves appear early in the ſpring; the foot-ſtalks of theſe are of a pale green, and almoſt as large as thoſe of the firſt ſort; they have ſcarcely any channels, and are flat on their upper ſide; the leaves are ſmooth, heart-ſhaped, and do not run out to ſo great length in a point as thoſe of the ſecond, but are longer than thoſe of the firſt, they are very broad towards their baſe, and have very large pale green ribs on their under ſide; they are a little waved on their edges, and have a ſharp acid flavour. The flower-ſtalk is of a pale green; it riſes five or ſix feet high, and is as large as a common walking cane, having at each joint one leaf of the ſame ſhape with thoſe

below, but ſmaller, ſitting cloſe to the ſtalk: the upper part of the ſtalk divides into ſmall branches, each ſuſtaining a panicle or ſpike of white flowers ſtanding ereſt, which appear the latter end of may, and are ſucceeded by large triangular bordered ſeeds, like thoſe of the firſt ſort, ripening in auguſt.

The roots of this approach nearer to thoſe of the foreign Rhubarb than either of the other, both in ſhape and quality; and as theſe ſeeds which were ſent to Peterſburgh, were gathered from the plants growing on the ſpot where the Rhubarb is taken up, ſo there is little reaſon to doubt of its being the true ſort, though the roots which have grown in England have not been equal in quality with thoſe of the foreign; but this may have been occaſioned for want of age, or by being taken out of the ground at an improper ſeaſon; therefore farther trials may improve it; and as the plants produce great plenty of ſeeds here, they may be propagated with great eaſe. Linneus ſeemed firſt to think the ſecond ſort was the true Rhubarb, but the roots of that which have grown here are very little better than thoſe of the Rhapontick, and I have reaſon to doubt if it is not a variety of it; for it is certain, theſe plants when growing near each other, are impregnated by each other's farina; for from the ſeeds of the Rhapontick, which grew cloſe to the ſecond ſort, I had a mixture of plants of both ſorts produced, though the plant of the ſecond ſort did not produce any ſeeds, for the ſtalk decayed ſoon after the flowers faded; and the ſeeds of the Rhapontick were gathered by myſelf from one plant, and were ſown in his Grace the Duke of Bedford's garden at Wooburn Abbey, where there had not not been any of theſe plants before growing, ſo that there could be no mixture of ſeeds, and yet a third part of the plants proved to be of the ſecond ſort.

Mr. Miller has more fully deſcribed this ſpecies in his Figures of Plants.—The root is very thick and fleſhy, and divides into ſeveral thick taper fangs, as large as a man's finger, covered with a reddiſh-brown bark: it is of a yellowiſh red colour within. The root ſtrikes pretty deep into the ground, and early in the ſpring ſends up many leaves, which at their firſt appearance are cloſely folded up, but afterward expand, to the length of near two feet, and the breadth of a foot and half at the baſe, where they are rounded to the footſtalk; their borders are ſinuated and a little waved, and they are ſomewhat downy on their under ſide. The footſtalks are ſeven or eight inches long, riſing immediately from the root; they are as large as a man's finger, flatted and channelled on their upper ſide, but convex on their lower, of a purpliſh red colour. The flower-ſtalks ariſe from the root, among the leaves, and are three feet and a half high, having a ſmaller leaf at each joint, the ears of which almoſt embrace the ſtalk.

[Linneus ſays, that the leaves are more coriaceous or compact than in the other ſpecies, whence his trivial name; that the lobes are rounded, more obſcure, crenate with the margin cartilaginous and the toothlets acute; that they are very ſmooth on both ſides, and have ſtouter veins. The branches of the panicle are nodding.

The ſeed is rounded cordate and three-ſided; the ſides beſprinkled with raiſed dots, of a browniſh-green colour, and ſhining; the angles membranaceous, ſtriated, ferruginous [c].

Native of Tartary. Introduced in 1779, by Chevalier Thunberg [d]. Mr. Miller's plant deſcribed above, not being the true *compactum* of Linneus, but more probably his *undulatum*.]

5. The fifth ſort grows naturally on mount Libanus, and other mountainous parts of Syria. This has a thick fleſhy root, which runs pretty deep in the ground, from which ariſe ſeveral leaves in the ſpring, which come up folded together, and afterwards expand; they have very ſhort foot-ſtalks, ſo ſpread near the ground; but during the ſpring, their borders are ereſt, and form a ſort of hood having ſeveral folds, and are curled and waved on their edges; they are of a purpliſh green, and have purple veins and borders; their ſurface appears ſtudded with rough protuberances, and when the leaves are fully expanded in ſummer, they are a foot long, and above two feet broad; their under ſide is paler than the upper, and their borders appear fringed. I have not ſeen this plant in flower, but the ſeeds of it were brought from mount Libanus, by the Right Rev. Dr. Pocock, the late Biſhop of Oſſory; theſe were larger than thoſe of the other ſpecies, and covered with a ſucculent pulp, of a deep red colour, and very aſtringent taſte; this ſucculent covering may have occaſioned its being taken for a berry, by many of the old writers; the ſhape of the ſeed is like that of the other ſpecies.

[Dillenius ſays, that William Sherard procured it from mount Libanus, eight years before he writ; and if that be underſtood of the publication of the Hortus Elthamenſis in 1732, it agrees with what is ſaid in the Kew catalogue from Knowlton's manuſcripts, that it was cultivated in 1724, by James Sherard, M. D.—Dillenius adds, that it had not then appeared in any of the European gardens, except in that of Leyden, after the time of Vorſtius, and in that of Eltham in his own time. Bellonius, Rauwolfius and Guilandinus had obſerved it growing naturally; and ſince their time Pocock and other travellers; not only on mount Libanus and Antilibanus, but on mount Sinai and Carmel, and in Perſia. Dr. Ruſſel informs us; that it was raiſed at Aleppo from ſeeds that came from the neighbourhood of Balbeck; and alſo by Mr. Gordon, of Mile-end, before the year 1781.

The ſtalks, as Rauwolff informs us, from thoſe which he ſaw brought to Aleppo, in order to make the Rob Ribes of Serapio, are near a cubit in height, an inch thick, hirſute, green, tinged with purple towards the bottom. It has never flowered in Europe, owing probably to its being ſo much out of place in our gardens, for it grows naturally in moiſt places on the mountains, and is covered with ſnow during a great part of the year.

6. Leaves large, thoſe next the root lying on the ground, on red petioles; the nerves very much widened. Inflorescence ſcarcely higher than the leaves. Native of Leſſer Tartary [e].

7. This is extremely allied in its appearance to the Rheum palmatum; being of ſimilar height, and having the ſame kind of leaves, ſtipules, &c. the leaves however are not ſo deeply laciniated nor ſo much pinnatifid as thoſe of the former ſpecies.

The firſt or radical leaves are generally cordate, and pointed, but not palmated, and the plant as it advances in age ſeems to become more palmated from year to year.

It was conſidered by Profeſſor Murray as a hybrid plant, produced by the mixture of Rheum palmatum with ſome other ſpecies, which had been impregnated by its pollen [f].

Not known where it is a native, but cultivated in 1778, by John Fothergill, M. D. [g]

There ſeems to be a diſpoſition in the Rheums to produce hybrid or mule plants. Mr. Miller has hinted it. A gentleman near Norwich, ſays that a near relation of his who is a phyſician, had ſome plants of R. palmatum and compactum, ſtanding ſo near together, four or five years ago, that the ſeeds ſaved from them produced only mule plants; and that they were then growing in his garden within a mile of Norwich [h]. This account being dated, ſept. 16, 1778, carries the cultivation of a hybrid Rheum to 1773 or 1774.

The phyſician gives this particular detail of theſe mule plants. In the ſummer of 1771, I had a plant of R. palmatum growing about four yards from a plant of R. compactum, both in full flower. The firſt being generally allowed to be the true Turkey Rhubarb, I gathered the ſeeds of it, and ſowed them early in ſpring 1772. In about five weeks the plants appeared in great plenty, and were in the beginning of the winter following tranſplanted. The leaves were neither

[c] Gærtner. [d] Hort. kew. [e] Linn. ſuppl. [f] Murray. [g] Hort. kew. [h] Bath papers, 1. 191.

Digitized by Google

thoſe of palmatum or compactum, very large and broad like the latter, but terminating in long ſharp points, and in ſome degree indented and reſembling the former. In 1775 theſe plants were all in flower: when their ſeeds were ripened, they were gathered, as they have been every year ſince, and ſowed every ſpring, but without having ever produced a ſingle plant. Many botanical gentlemen have viewed theſe plants, and have pronounced them to be mules. The root does not appear to have been at all affected in quality or appearance, on being compared with that of R. palmatum [l].

Dr. Pulteney writes, in 1783, that he had been informed, that palmatum and undulatum planted near each other will produce a mongrel plant, the ſeeds of which are not fertile [k].

Probably there may be other mongrel ſorts produced. There are ſeveral ſpecies now cultivated in the botanic garden at Cambridge, different from any of thoſe deſcribed above, but not yet ſufficiently aſcertained to be regiſtered here. Some of theſe may be mule plants; but as they all ſtand very near each other, ſuch no doubt would be produced if the ſeeds of the ſeveral ſpecies were collected and ſown.]

PROPAGATION AND CULTURE.

Theſe plants are all propagated by ſeeds, which ſhould be ſown in autumn ſoon after they are ripe, and then the plants will come up the following ſpring; but if they are kept out of the ground till ſpring, the plants ſeldom come up till the next ſpring, ſo that a whole year will be loſt. The ſeeds ſhould be ſown where the plants are deſigned to remain; for as their roots are large and fleſhy, when they are tranſplanted, they do not recover their removal ſoon; nor will the roots of thoſe plants which are tranſplanted, ever grow ſo large and fair, as thoſe which remain where they were ſown. When the plants appear in the ſpring, the ground ſhould be hoed over, to cut up the weeds; and where the plants are too cloſe, ſome ſhould be cut up, leaving them at the firſt hoeing ſix or eight inches aſunder; but at the ſecond, they may be ſeparated to a foot and half diſtance or more. As ſoon as any weeds appear, ſcuffle the ground over with a Dutch hoe in dry weather. When the plants cover the ground with their broad leaves, they will keep down the weeds of themſelves.

In autumn, when the leaves decay, clean the ground, and in the ſpring, before the plants begin to put up their new leaves, dig the ground between the plants, or at leaſt hoe and clean them. The ſecond year, many of the ſtrongeſt plants will produce flowers and ſeeds, but the third year moſt of them will do ſo. Gather the ſeeds carefully when ripe, and do not permit them to ſcatter, leſt they ſhould grow to injure the old plants. The roots will remain many years without decaying; and it is ſaid that the old roots of the true Rhubarb are much preferable to the young ones. They delight in a rich ſoil, not too dry, nor over moiſt; and where there is a depth in ſuch land for their roots to run down, the leaves and roots will attain a great ſize.

The firſt ſort is now frequently cultivated in gardens for the footſtalks of the leaves, which are peeled and made into tarts in the ſpring.

The true Rhubarb is now ſown in many gardens, and may probably ſucceed ſo well in time, that a ſufficient quantity of that valuable drug may be raiſed to ſupply our conſumption.

[Dr. Mounſey's directions for the culture of the Turkey Rhubarb, are to ſow the ſeeds in april or may, three or four in a pot, which ſhould be plunged in a hot-bed until the ſeeds vegetate. When the plants are about two months old, tranſplant them where they are to remain, in a fine light ſoil. Keep ſome of the plants in the pots until october, and ſome to the ſpring following, and then plant them out. When by theſe precautions you have ſecured a ſufficient number of plants, you may venture to ſow the ſeeds in the open air. If they vegetate late in the ſeaſon, cover them with muloh or moſs, to preſerve them in winter. When tranſplanted, ſet the plants at leaſt four feet aſunder, hoe them, keep them clean, and turn up the ground yearly between the rows, taking care not to touch the roots. In the ſecond or third year the plants will begin to bear ſeeds. The earlieſt period at which the roots are uſeful, is at four year's growth, but even then they will be ſoft and ſpungy: they had better therefore remain eight years undiſturbed; and even more years will add greatly to their perfection [l].

Mr. Davis, of Minehead, recommends the ſeeds to be ſown on a very gentle hot-bed in march, and when the roots are about the ſize of a crow's quill, they ſhould be drawn up carefully to preſerve the tap-root, and planted in fine rich earth in a deep ſoil: if the weather ſhould prove dry, they muſt be watered. When the plants are once in a growing ſtate, all farther care and trouble, but that of keeping them free from weeds, is at an end.

The diſtance of the plants ſhould be eight feet; and as they diſappear above ſeven months in the year, the ground may be uſefully employed in many articles of gardening, from the middle of auguſt to the beginning of april [m].

The ſeeds however do not require a hot-bed to make them vegetate; but if ſown in the natural ground during the ſpring, when the weather is open, ſoon come up and thrive very faſt. This plant delights moſt in a rich light deep ſoil, and warm expoſure, but will thrive in almoſt any ſoil or ſituation. If the roots be covered with litter, or the earth be drawn over them in winter, they will riſe the ſtronger in the following ſpring. The ſeeds ſhould be ſown where the plants are to remain, and when they appear, the ground ſhould be kept clean from weeds. When thinned out, the diſtance of the plants ſhould be eight feet [n].

Sir William Fordyce, who ſowed the ſeeds at firſt upon a hot-bed; on the whole, found that they ſucceeded beſt when ſown in the open ground, in an eaſt or ſouth-eaſt expoſure, during the laſt half of march, or in april, or even ſo far as the end of may; if the ſpring proved cold and dry. It may be tranſplanted during the whole courſe of the ſummer [o].

If the ground be ſtirred about a ſeeding plant, the ſeeds falling will produce plenty of young plants, both in the autumn and the following ſpring: theſe may be tranſplanted about midſummer [p].

Mr. William Hayward, of Banbury, ſows the ſeed about the beginning of february, on a bed of good ſoil, if rather ſandy the better, expoſed to an eaſt or weſt aſpect, in preference to the ſouth; a full ſun being prejudicial to the vegetation of the ſeeds, and to the plants whilſt young. Sow broadcaſt moderately thick, treading the ſeeds regularly in, and raking the ground ſmooth. In a wet ſeaſon, it is beſt to make a bed two feet thick, with new dung from the ſtable, covering it near one foot thick with good ſoil. The intent of this bed is not ſo much for the ſake of warmth, as to prevent the riſing of earth-worms, which in a moiſt ſeaſon will frequently deſtroy the young crop.

If the ſeed be good, the plants often riſe too thick; if ſo, when they have ſix leaves, take them carefully up, where too cloſe, leaving the ſtanding crop eight or ten inches apart: plant thoſe that are taken up at the ſame diſtance, in a freſh ſpot of ground, in order to furniſh other plantations. When the plants in general are grown to the ſize that Cabbage plants are uſually ſet out for a ſtanding crop, plant them where they are to remain, in beds four feet wide, one row along the middle of the bed, leaving two yards diſtance between the plants, allowing an alley between the beds about a foot wide, for conveniency of weeding the plants.

In the autumn, when the decayed leaves are removed, if the ſhoveling of the alleys be thrown over the crowns of the plants, it will be found of ſervice [q].

Digitized by Google

Mr. John Ball, ſurgeon of Williton, ſows the ſeeds the ſecond week in february, in drills ſix inches apart, and one inch deep, upon beds three or four feet wide. If the weather ſhould prove mild, the plants will appear in a fortnight or three weeks; and in a dry ſeaſon they muſt be moderately watered. If too thick, thin them from two to three inches; and when about four inches high, tranſplant them where they are to ſtand, from four to ſix feet from each other, in a deep ſoil, well manured with good rotten dung, ſifted coal aſhes, and lime ſlaked and mixed with mud or waſte from a mill-pond, or with earth from the gutters of meadows. Keep them clean from weeds, and if occaſion, water them moderately, and look over the plantation every evening, to pick off the ſlugs, which are exceedingly fond of the young plants, and will ſoon deſtroy them.

The ſeeds may be ſown alſo in ſeptember, or the firſt week in october, and they will be fit to tranſplant in february or the beginning of march[r].

The Rev. James Stillingfleet, of Hotham in Yorkſhire, ſows the ſeed early in the month of april, on a ſandy loam, in a ſouth-eaſt aſpect; ſheltering the young plants from the ſun till they have obtained ſtrength.

When about the ſize of young cabbages or ſmaller, he tranſplants them into beds four or five feet wide, at the diſtance of five or ſix feet aſunder: but the plants which remain in the ſeed-bed, when well thinned, are larger and better than the others. It will conduce to their ſtrength and growth to raiſe the bed ſomewhat above the alleys, that the plants may be kept dry; for Rhubarb will not bear much wet; though a very dry ſand will not ſuit it. Much dung tends to canker the plants: a good free ſoil, in a moderate ſtate of cultivation, ſeems to ſuit them beſt; or if mulch be uſed, it ſhould be thoroughly rotten, and almoſt reduced to mould. The young plants in the end of autumn ſhould have the ſcrapings of the alleys thrown over them, and alſo in ſpring, when the plants are about an inch above ground[s].

Mr. Thomas Jones, of Fiſh-ſtreet hill, London, ſows the ſeeds in march and april, or during the autumn in auguſt and ſeptember; the former to be tranſplanted in autumn, the latter in ſpring. Inſtead of placing the ſeedling plants where they are to remain, as is uſually recommended, beds ſhould be prepared reſembling thoſe which are made for Aſparagus, of fine mould, from twelve to eighteen inches deep. When the young plants are four or five inches high, and have thrown out as many leaves, tranſplant them upon thoſe beds at eight inches aſunder; ſelecting firſt the largeſt, carefully drawing them out, ſo as to deſtroy or even diſturb the fibres as little as poſſible. Watering the bed previous to the removal, will greatly facilitate the operation. In the culture of Rhubarb, the whole difficulty conſiſts in bringing the plants through their firſt ſeaſon: if the weather be hot and ſultry, they muſt be ſhaded, and at all events they muſt be continually watered. For tranſplanting, a wet or cloudy day ſhould be preferred; and if the weather ſhould continue ſo for two or three days ſucceſſively, not more than four or five in a hundred will probably be loſt. In a month the roots will have made freſh ſhoots, and new leaves will have ſucceeded the former, which commonly, notwithſtanding all our care, will wither away. The plants may now remain in theſe nurſery-beds till the enſuing ſpring, or if the ſummer be favourable, and the land intended for the plantation be well trenched three feet deep, it may be completed without delay. It is a good way to ſow the ground with Carrots, the ſurface by this means being preſerved from weeds, and rendered finer by repeated hoeings, and the bottom kept light and open. At different periods during the ſummer, when the plants are of a proper ſize, and the weather is cloudy or ſhowery, with a tranſplanter or circular ſpade, remove them with a ball of earth adhering, at the preſcribed diſtances, into the midſt of the Carrots, deſtroying ſuch as might obſtruct the growth of the Rhubarb; and if the weather ſhould prove unuſually hot, the foliage of the Carrots will preſerve the young plants from the ſun, till they have acquired a ſufficient growth. After this, it remains only to keep the plantation clean, and the trenches open[t].

In the choice of a ſituation, the aſpect is not very material, provided it be not ſhaded too much on the ſouth or weſt. The indiſpenſable points are the depth and good quality of the ſoil, which ſhould be light, loamy and rich, but not too much ſo, leſt the roots ſhould be too fibrous: it can ſcarcely be too dry, for more evil is to be expected from a ſuperabundancy of moiſture, than from any actual want of it. If with theſe advantages, the plantation can be placed on a gentle declivity; ſuch a ſituation may be ſaid to be very eligible.

The injuries which the young plants are moſt liable to, are from ſlugs and other ſmall vermin, from inattention to the ſeaſon and manner of planting, and from too great an expoſure to froſt. Little damage is to be feared from heat; and in general they are hardy and eaſy of cultivation, when arrived beyond a certain term.

If the ground deſtined for the plantation be a greenſward, no time will be loſt by a little delay. Suffer a ſeaſon or two to elapſe, by growing Oats, Potatoes, &c. before the plantation be attempted, that the turf may be entirely rotted, and the wire worms, which always infeſt old graſs land, be completely deſtroyed.

Sow liberally, not thick on a ſmall piece of ground, but in ſufficient quantity; it being impoſſible to foretell what may happen, from an unuſually wet or ſevere winter, &c. Never let a ſeaſon be omitted, leſt a ſupply ſhould fail, and a ſucceſſion be loſt.

Provided the weather be open, the beſt time for ſowing is the end of february or the beginning of march; and if the ſeed ſhould not vegetate in three weeks, let the ſowings be repeated till they do. In cold ſoils a moderate hot-bed may be ſometimes required, but very ſeldom; and ought never to be uſed but when abſolutely neceſſary, thoſe plants being ſtrongeſt that are raiſed in the open ground. It is better to ſow broad-caſt than in drills.

The nurſery-bed muſt be diligently attended to. The pains beſtowed by conſtant waterings, and protecting the young plants from the ravages of inſects, will amply repay the planter. Roots that thrive well here, will in three years arrive at an equal ſize with others, that have not ſucceeded ſo well, at the end of five. When a plantation is to be formed, or a vacancy filled up, ſelect the fineſt and moſt thrifty plants. No plant will come to any thing, when it has loſt its principal bud.

When a plantation does not poſſeſs the natural advantage of being on a declivity, narrower beds, and deepened trenches, are among the artificial means that ſhould be adopted; but moſt ſituations will require ſome care to prevent the ill effects of water remaining on the crowns of the plants: therefore when the ſeed-ſtalks are cut off, which ought always to be done immediately upon the withering of the radical leaves, they ſhould be covered with mould in form of a hillock. This proceſs will anſwer two good purpoſes, that of throwing off the rain, and keeping open the trenches by taking the earth from them.

Till the plants have blown, the medical qualities of the roots ſcarcely come into exiſtence; and at the ſame period the danger of decay commences likewiſe. When the buds from the roots have grown up and flowered, a cavity is formed in the centre of the plant, in which rain will make a lodgement, to the inevitable deſtruction of thoſe parts that, on this account, year after year, become unprotected.

Theſe portions of the crown whence the ſeed-ſtalks ariſe, prove ever the moſt valuable; and every ſucceeding year producing other ſeed-ſtalks, would add to the ſtock of uſeful root, if experience did not tell us, that hitherto the latter have increaſed no faſter than the former have been diminiſhed.

Every ſpring and autumn the plants ſhould undergo a general examination. The young ones will preſently

[r] Tranſ. Arts. 15. 179. [s] Idem, 15. 157. [t] Idem, 15. 167.

Digitized by Google

diſcover their real ſituation, for either their leaves will wither as faſt as they are produced, or their growth will become ſtunted: but with regard to the older ones, or thoſe that have blown, as in moſt caſes there will be found enough ſound root to produce a luxuriant foliage, their ſtate can only be diſcovered by preſſing a finger into the centre of the crown: the leaſt unſoundneſs will ſoon be perceptible by this means.

In both caſes the plants ſhould be removed, and the vacancies filled with others; for in the former much time will be ſaved, and the bad ſituation of the latter, by remaining, will only be aggravated, whilſt it furniſhes the cultivator with an opportunity of examining into the occaſion of the ſeveral defects, and may lead to future prevention [u].

Reſpecting ſoil, the general voice is, that ſuch an one as is fit for Carrots, will ſuit Rhubarb. Dr. Lettſom ſays it delights in a ſandy ſoil, on a ſomewhat elevated ſituation:—Dr. Hope, that the roots raiſed in a dry ſoil are preferable to thoſe raiſed in a moiſt one: Another phyſician, that the ſoil in which his plants were raiſed is very light for about twelve inches deep, and under that a ſtratum of red ſand of great depth [x].

Mr. Hayward's plants grew on a ſtrong red loam, on a gentle declivity towards the weſt:—Mr. Davis's on a light black ſoil, in a ſituation quite open, and without any declivity:—Mr. Stillingfleet's on a ſandy loam, which he finds to be the beſt ſoil; he prefers a ſouth-eaſt aſpect, but thinks an eaſt aſpect might poſſibly be ſtill better [y].

Mr. Bell, in his travels among the Tartars, relates that where there are ten or twenty plants of Rhubarb growing, you are ſure to find ſeveral burrows of the Marmot under the ſhade of their broad ſpreading leaves. For when the ſeed happens to blow among the thick graſs, it can very ſeldom reach the ground; whereas what falls among the looſe earth thrown up by the Marmots immediately takes root, and produces a new plant. Mr. Bell farther ſays, that he dug up as much of the root as he wanted, with a ſtick [z].

It is plain from this account, that the ſoil there is light and dry; two properties which appear to me indiſpenſable to have the Rhubarb root of a good quality: a poor ſand is bad, but a ſtiff clay is worſe; good ſandy loams, fit for Carrots, as was before obſerved, are the beſt.

It may be doubted whether manure ſhould be uſed or not. Mr. Ball, in his ſandy ſoil, uſed one part good rotten dung, and two parts rich earth from the gutters in watered meadows, thrown together two years and often turned, two parts of old cobb or mud wall, and two parts of ſifted coal aſhes. The ſecond year he gave the plants a freſh dreſſing of good rotten dung. He uſed alſo one part rotten dung, one part ſifted coal-aſhes, and two parts lime previouſly ſlaked, and mixed with mud or waſte from a mill pond and often turned.

Mr. Hayward, on his ſtrong red loam, manured at a conſiderable expenſe with well rotted horſe-dung; his land being in a very impoveriſhed ſtate from a bad tenant.

Mr. Stillingfleet does not adviſe much dung, as it tends to canker the plants; and thinks that a good free ſoil in a moderate ſtate of cultivation, ſeems to ſuit them beſt; or if mulch be uſed, it ſhould be quite rotten, and almoſt reduced to mould [a].

Sir William Fordyce remarks, that ground unmanured, or not too rich, is leaſt apt to breed the fly, to which this plant is more ſubject than even the Turnep [b].

I have no doubt but that dung injures the quality of the root, and that it will be beſt on good freſh ſound land, well worked.

The diſtance moſt generally recommended at which the plants ſhould finally ſtand for a crop, whether hoed out or tranſplanted is four feet; and the Society of Arts recommended that the plants ſhould ſtand that diſtance at leaſt. Mr. Jones remarks, that although the foliage will frequently meet at a much greater diſtance, the roots never occupy ſo large a ſpace [c]. This gentleman had when he began to cultivate Rhubarb, ſet the plants at the diſtance of ſix feet. Mr. Ball's plants alſo ſtood ſix feet aſunder every way [d].

Rhubarb may be propagated not only from ſeeds, but from offſets. Mr. Thomas Hayes, ſurgeon at Hampſtead, having found himſelf diſappointed in raiſing plants from ſeed, ſeparated ſome of the eyes or buds, which ſhoot out on the upper parts of the root, together with a ſmall part of the root itſelf, having ſome of the fibres to it. Theſe offſets may be taken from roots of three or four years old, without any injury to the plant. By this method a year is ſaved, the plants are not in ſuch danger of being devoured by vermin as thoſe from ſeed, nor ſo uncertain in growing; they are not ſo tender, neither do they need tranſplanting, or any other care than keeping the ground clear of weeds. There is no difference in the ſize of the roots thus raiſed, from thoſe which grow from ſeeds [e].

Mr. Hayward alſo ſlipped ſeveral offſets from the heads of large plants in the ſpring, and ſet them with a dibble about a foot apart. In autumn they had made great progreſs, and furniſhed his beds with forty plants in the moſt thriving ſtate [f]. Four years after he took up theſe roots, and found them to be very large, and of excellent quality. On farther experience, when he took up his roots, either in ſpring or autumn, he divided the head into many parts; theſe he planted directly, at two feet diſtance, if intended for future removal; but if to remain for a crop, he allowed four feet and a half [g].

There is a difference of opinion reſpecting the age at which the roots ought to be taken up for uſe. According to Dr. Mounſey, the earlieſt period at which the roots are uſeful, is at four years growth, but even then they will be ſoft and ſpungy. They ſhould remain therefore eight years undiſturbed; though ſtill more years will add greatly to their perfection [h].

Sir William Fordyce is alſo of opinion, that though Rhubarb may be taken up at the end of four years, it will not, how properly ſoever managed, poſſeſs that ſolidity which is neceſſary for its excellence. It will be found in its moſt perfect ſtate at the end of ſeven years, but it will continue good after that age, if it has been carefully cultivated, and is ſkilfully cured [i].

A phyſician in the Bath memoirs, aſſigns eight years as the meridian of perfection for the roots [k].

Mr. Stillingfleet ſays the beſt time for taking up the roots, is when they are five or ſix years old, according to the ſize of the plants: if younger, they are defective in ſtrength and efficacy; if older, they are ſtrong in taſte, and more rough in their operation [l].

All accounts agree, ſays Mr. Jones, that Rhubarb ſo cultivated as to arrive at ſix or ſeven years growth, and properly cured, will poſſeſs all the virtues the moſt ſanguine can deſire [m].

And yet Dr. Hope and ſome others are for taking up the roots at four years old [n].

The ſame gentleman deſcribes the ſeaſon for taking them up to be from the end of july to the firſt of january; after the weather has been ſome time dry.

Dr. Lettſom ſays, it may probably be of little conſequence, as to the vigour of the roots, whether they are taken up in ſummer or autumn; but as warm weather is beſt for drying them, the former ſeems moſt eligible [o].

Bergius adviſes the roots to be taken up in autumn, and to be eleven or twelve years old. Dr. Pulteney is inclined to be in favour of the ſpring, before the plant begins to puſh its leaves; though he is ſenſible that this will not hold in thoſe bulbous or tuberous

kinds,

Digitized by Google

kinds, which form a new root annually, as ſoon as the plant is perfected.

The Chineſe get up their Rhubarb in winter[p]. Pallas ſays that the Tartars take up theirs in april and may; but in Bell's account, this is ſaid to be done in the autumn. Forſter, in his hiſtory of voyages to the north, affirms that the roots are dug up there in winter, before they put forth leaves, becauſe they then contain the entire juice and virtue of the plant; thoſe that are taken up in ſummer being of a light ſpungy texture, and unfit for uſe.

Mr. Jones, prefers taking up the roots as near to the winter ſolſtice as he can; for though the powers of nature might be more active in february, yet the roots dry better and ſhrink leſs than in the ſpring. He generally finds them to loſe about four fifths in drying[q].

The roots, in the judgment of Mr. Hayward, may be taken up either early in the ſpring, or in autumn when the leaves are decayed; in dry weather, if poſſible[r].

Mr. Ball takes up the roots, when the ſtalks are dying away[s].

The greateſt difficulty in this buſineſs ſeems to be drying and curing the root.

In Tartary, the root, being thoroughly cleaned, and the ſmaller branches cut off, is cut tranſverſely into pieces of a moderate ſize; theſe are placed on long tables or boards, and turned three or four times a day, that the yellow viſcid juice may incorporate with the ſubſtance of the root. If this juice be ſuffered to run out, the roots become light and unſerviceable; and if they be not cut within five or ſix days after they are dug up, they become ſoft, and decay very ſpeedily. Four or five days after they are cut, holes are made through them, and they are hung up to dry expoſed to the air and wind, but ſheltered from the ſun. Thus in about two months the roots are completely dried, and arrive at their full perfection. The loſs of weight in drying is very conſiderable; ſeven loads of green roots yielding only one ſmall horſe-load of perfectly dry Rhubarb[t].

The Chineſe, after having cleaned the roots, by ſcraping off the outer bark, as well as the thin yellow membrane underneath, cut them in ſlices, an inch or two in thickneſs, and dry them on ſtone ſlabs, under which large fires are kindled. They keep continually turning theſe ſlices on the warm ſlabs; but as this operation is not ſufficient to dry them thoroughly, they make a hole through them, and ſuſpend them on lines, in a place expoſed to the greateſt heat of the ſun, till they are in a condition to be preſerved without danger of ſpoiling[u]. Rochon on the contrary aſſerts, that they are hung in the open air and in the ſhade[x].

Sir William Fordyce directs, that as ſoon as a root is dug up, it ſhould be waſhed till it is thoroughly clean. Let the fibres be taken away, and not the ſmalleſt particle of bark left on the larger roots. Cut theſe into ſquare pieces, as nearly as they will admit, of four inches in breadth, and an inch and half in depth. Make a hole in the middle of each, about half an inch ſquare. Then ſtring them on a packthread, with a knot on each, and at ſuch a diſtance as to keep them from rubbing or entangling. Thus ſecured, hang them up in form of feſtoons, in the warm air of a kitchen, laundry or ſtove, till the ſuperfluous moiſture is exhaled, to prevent their becoming mouldy or muſty. They may be afterwards dried more at leiſure, and when quite dry may be wrapped ſeparately in cotton, and kept in wide mouthed bottles. The tap-roots and parings will make excellent tinctures[y].

Mr. Davis recommends, that after dividing the root into proper parts, the outer rind ſhould be ſliced off, and then it ſhould be hung up on a ſtring expoſed to ſun and air, but defended from wet: each piece hanging ſeparately, and care taken that it does not grow mouldy. When hardened on the outſide, remove it to the kitchen chimney-corner, where a moderate fire is conſtantly kept, till it is perfectly dry. It may then be raſped, and all the diſcoloured outſide taken off[a].

Dr. Hope is of opinion that the entire root ſhould be hung up in the open air for two, three, or more weeks, and then cut into marketable pieces, before it be put into the drying. The cuticle ſhould be rubbed off as ſoon as poſſible[b].

Mr. Hayward's method is, to clear the roots from dirt, without waſhing, to cut them into pieces, with a ſharp knife to free them from the outer coat, and then expoſe them to the ſun and air for a few days, to render the outſide a little dry.

In order to accelerate the curing of the largeſt pieces, a hole may be ſcooped out with a penknife: theſe and the ſmaller parts are then to be ſtrung on packthread, and hung up in a warm room (as over a baker's oven) where they are to remain till perfectly dry. Each piece may be rendered more ſightly by a common file, fixing it in a ſmall vice during that operation: afterwards rub over it a very fine powder, which the ſmall roots furniſh in perfection, for this and every other purpoſe where Rhubarb is required[b].

Mr. Thomas Halley, of Pontefract, who produced ſamples to the Society of Arts, ſuperior to any Rhubarb hitherto cured in England; having thoroughly diveſted the roots of the adhering earth, placed them for ſome weeks on the floor of a cool warehouſe: the fibres were then taken off, they were cut up, and dried on the flue of a green-houſe. The prime roots were ſevered in ſmall pieces, peeled clean, and cleared of every particle of unſoundneſs. Part was ſeparately laid in ſieves, and the remainder perforated, ſtrung, and ſuſpended in feſtoons from the cieling of a warm kitchen. The manner of dreſſing conſiſts in paring off the external coat with a ſharp knife, as thin and clean as poſſible, and then finiſhing it off by a piece of fiſh-ſkin, with its own powder; which powder may be procured from the chips and ſmall pieces, either by grinding or pounding it in a large mortar[c].

Mr. Ball, ſo often mentioned, cleans the earth from the roots with a dry bruſh, cuts them in ſmall pieces of four or five inches in breadth, and about two in depth, taking away all the bark, making a hole in the middle, and ſtringing them ſo as to keep every piece apart. If the weather be clear and fine, he places them in the open part of his garden, on ſtages erected by fixing ſmall poſts about ſix feet high in the ground, and ſix feet aſunder, into which he puts horizontal pegs about a foot apart, beginning at the top; and the Rhubarb being ſtringed croſſwiſe on ſmall poles, he places them on theſe pegs; ſo that if it ſhould rain, he can eaſily remove each pole with the ſuſpended pieces into a covered place. He never ſuffers them to be out at night, as the damps would be apt to mould them, and if at any time he perceives the leaſt mould, he rubs it off with a dry cloth. In ſome of the pieces he made holes in the middle about half an inch diameter, and found that they dried better than the others. He likewiſe hung ſeveral ſtrings in the kitchen, without ever expoſing them to the open air, and found them to dry much better. Some years ſince he dried a quantity on a malt-kiln, keeping up the thermometer to eighty degrees, which anſwered well, but he thinks dried rather too quick[d]. Finally, he preferred hanging his ſtringed roots to the cieling of a kitchen, where there is a conſtant fire[e].

Mr. Stillingfleet, after diveſting the roots of the earth, waſhes them in water, working them round with a birch broom, ſcrubbing them afterwards with a hard bruſh; nor does he find any inconvenience in this, if done immediately, and the roots not ſuffered to remain in the water. He then wipes them with a coarſe cloth, and lays them in the ſun or wind to dry, cutting them into pieces, as may beſt ſuit the farther proceſs. The rind is then pared off rather thin, the

pieces

pieces are ſtrung together, and hung up in the kitchen. He thinks that warmth fully ſufficient, and that the more gradually the roots are dried, the better they are for uſe. His were fully dried in half a year or leſs. He does not ſcoop out the middle, regarding that as the moſt uſeful part, though not the ſtrongeſt. He quarters the large pieces, that they may dry more thoroughly [f].

Dr. Falconer, of Bath, is of opinion, that if the following circumſtances were attended to, Britiſh Rhubarb might equal any of the foreign.

Firſt, a ſelection of the beſt pieces is indiſpenſably neceſſary.

Secondly, the central part of every piece ſhould be cut out; for it is found by experience that this, perhaps from its proximity to the ſap, is moiſteſt and moſt ſubject to decay; and when any part comes into this ſtate, the infection ſoon ſpreads and damages the whole piece. Doubtleſs it is to avoid this, that the pieces of Ruſſian Rhubarb have all holes, and thoſe pretty large, cut through their centre, which have been generally thought only to ſerve the purpoſe of hanging them up, but appear to anſwer this material purpoſe beſides. The holes made in Engliſh Rhubarb, when there are any, are not ſufficiently large to clear away the ſpungy and decaying parts.

Thirdly, the outſide ſhould be ſcraped or rather raſped, as the foreign Rhubarbs are. The want of this not only gives it a ſhrivelled and mean appearance and colour, but is really of great diſſervice, by obſtructing the quickneſs of drying, from the pores not being laid open for the herbaceous moiſture to exhale. Though the bark be ſtripped off, the larger pores running moſtly longitudinally, do not open laterally, and of courſe the watery fluid is confined, and exſudes very ſlowly.

Fourthly, it is probable, that great improvement might be made in the preparation of Engliſh Rhubarb, by accelerating its drying. It was formerly thought that plants were beſt dried in a ſlow and gradual manner, which is now found to be a miſtake, and that as quick drying as is conſiſtent with the ſafety of the vegetable ſubſtance, beſt preſerves the efficacious qualities of the plant.

Too much light indeed is thought to do injury, as it impairs the colour, and perhaps, though that is dubious, diſſipates ſome of the finer parts; but culinary heat is free from that objection, and at the ſame time poſſeſſes all the advantages of quick drying [g].

Dr. Hope ſays, on the ſubject of Rhubarb, I have thought much, made many experiments, and received much uſeful information: after all, it is a very difficult and uncertain attempt to dry Rhubarb ſucceſſfully [h].

Certainly much of the true Rhubarb produced in England has not been cured ſo well as the foreign. But it may be hoped that attention to the directions here given, followed up by practice, may at length give complete ſucceſs.

The Duke of Athol has raiſed Rhubarb in Scotland, which was thought by eminent druggiſts, and gentlemen of the medical profeſſion in London, to be nearly, if not quite equal to the Ruſſian, in ſmell, taſte, and effect. By paying a little more attention to the curing, they conceived that its beauty might be increaſed. Upon which, the year after, his Grace ſent up ſpecimens of ſtill ſuperior quality [i].

Its having braved the climate of St. Peterſburgh, and ſucceeded well in Scotland, is a ſufficient proof of its hardineſs. Dr. Robertſon informs us that it grows luxuriantly in Perthſhire (Lat. 56°): that gardeners and others raiſe it there in great perfection; and that there is a conſtant demand for it as a medicine: but that there is ſuch a rage for every thing foreign, that Rhubarb of Scottiſh growth is generally rejected in the ſhops, knowing it to be ſuch; which may have prevented its cultivation [k].

I have been very diffuſive upon this article, becauſe it appears to be of national importance. And I have given the opinions of different cultivators, rather than deciſive rules, becauſe the propagation, culture and curing of Rhubarb in Britain, have not been practiſed long enough, and to a ſufficient extent, to admit of certainty and preciſion. It were much to be wiſhed that it might be tried on a large ſcale, on ſome of our beſt Carrot ſoils, ſuch as thoſe about Woodbridge in Suffolk and Sandwich in Kent. Where, with due attention to the age of taking up and the curing, there is no doubt but the crop would amply repay the cultivators, and be a conſiderable ſaving to the nation.]

DESCRIPTIONS, *&c.*

1. This riſes with an erect ſtalk, near a foot and half high, four-cornered and hairy. Leaves lanceolate, hairy, about two inches long, and half an inch broad, entire and oppoſite. The ſtalk has two peduncles coming out from the ſide oppoſite to each other at the upper joint, and is terminated by two others; theſe each ſuſtain two or three red flowers with heart-ſhaped petals, ſpreading open in form of a croſs, and appear in june.

[The corners of the ſtalk are membranaceous. The leaves are longer than the internodes, three-nerved, ſomewhat hiſpid with ſcattered hairs, ſubſerrate with ſetaceous ſerratures. Peduncle terminating, dichotomous. Flowers ſolitary from the diviſions, ſubſeſſile. Anthers ſickle-ſhaped, yellow [l].

Native of North America. Cultivated in 1759 by Mr. Miller [m]:] who ſays, that it was diſcovered by Mr. Baniſter in Virginia. [Ray adds that Krieg brought it from Maryland.]

2. This ſends up an erect ſtalk about ten inches high. Leaves lanceolate, about an inch long, and a third part of an inch broad, ſet on by pairs; and from every joint of the ſtalk two ſhort ſhoots come out oppoſite, with ſmall leaves of the ſame ſhape; the whole plant is thick ſet with ſtinging iron-coloured hairs. The ſtalk divides at the top into two peduncles, ſpreading from each other, having one or two reddiſh flowers on each, with a ſingle ſubſeſſile flower between them; they have four heart-ſhaped petals, which ſpread open as in the preceding. It flowers about the ſame time. [Capſule within a ventricoſe calyx terminated by a four-cleft funnel-form border, membranaceous, very thin, ſubglobular, produced at top into a ſhort knob, four-celled, opening four ways at the top: partitions membranaceous, inſerted into the middle of the valves. Receptacles four, ſomewhat creſcent-ſhaped, fungoſe, excavated, inſerted by a thick lateral peduncle into the internal angles of the cells below the middle; the other parts quite free. Seeds ſmall, with raiſed dots in rows, pale, almoſt cylindrical, with a ſingle turn like a ſnail's cell, terminated by a wide concave navel. Skin ſingle, thickiſh, ſubero-cruſtaceous, brittle [n].

[Native of Maryland, Braſil, Surinam, in meadows [o]. Vernon and Krieg brought it from Maryland [p];] whence Mr. Miller alſo received the ſeeds. [He cultivated it in 1759.

Linneus remarks, that the calyx has briſtles ſcattered over it, which are ſtellate at the top.

Ray deſcribes the ſtem as round, ſlender, hirſute: the leaves alternate at moderate diſtances, longer, wider and ſharper than thoſe of Hypericum: from the ſinuſes of theſe ſpring branchlets, having very ſmall narrow ſharp leaves towards their upper part, and ſuſtaining large flowers at top, which in the dried ſpecimens ſeemed to be yellow. It is not certain that Ray's plant is the ſame with Plukenet's and Linneus's.

3. Stem fruteſcent. Branches four-cornered, with the corners rough-haired, trichotomous at bottom, dichotomous at top. Leaves an inch long, quite entire. Peduncles ſhort, at the forks and ends of the branches. Petals ovate, ciliate [q].

4. This ſeldom riſes above fourteen or ſixteen inches in height. The ſtem is pretty firm and ſquare, and emits many ſquare branches towards the top. The leaves are ſmall, three-nerved, ovate, crenate and oppoſite. The flowers ſpring ſingly from the alternate axils or boſoms of the leaves. The calyx is deeply five-cleft at the mouth. Petals five, obovate, inſerted into the throat of the calyx. Filaments ten, ſhorter than the corolla. Anthers oblong, ſagittate and ſubarcuate, verſatile. Germ crowned with the calyx. Style ſhort. Stigma ſharp. Capſule two-celled, filled with two little placentas. Native of Jamaica [*].

5. This is a ſhrub four feet in height, pubeſcent, as are alſo the peduncles and fruit. Leaves ſubſeſſile, ſomewhat cluſtered, lanceolate, ſcarcely a finger's length, rather directed all one way, rugged on the edge with very minute ſerratures, the nerves prominent a little underneath. Flowers axillary, ſolitary, peduncled, ſcarcely the length of the leaves, yellow. Perianth almoſt ſuperior, lanceolate, acute, ſpreading. Petals ſubovate, double the length of the calyx, ſeſſile. Filaments ſhorter: anthers incumbent, the length of the calyx or longer than the filaments. Germ inferior, the length of the calyx, a little prominent: ſtyle cylindrical: ſtigma warted. Capſule obovate, four-cornered, the length of the calyx, with four ſmall laminæ at top.—This plant is ſingular by its naked, warted, undivided, ovate ſtigma, girt as it were by a four-toothed margin; and by its capſule prominent within the calyx, marked as it were by four agglutinated laminæ. It is allied to Epilobium and Oenothera, but without a tubular calyx.—Native of Surinam, where it was found by C. G. Dalberg.

6. This is a ſmall and very leafy tree, reſembling the Melaſtomas, with jointed branchlets, alternately channelled. Leaves petioled, ſomewhat cluſtered, elliptic, quite entire, an inch long. Flowers ſcarcely longer than the leaves, peduncled. Calyx bell-ſhaped, ſpreading a little. Capſule inferior, four-parted or four-celled, ſhorter than the calyx, blunt. The ends of the branchlets and the calyxes are glutinous, whence the trivial name.—Found by Mutis in New Granada [r].

7. 8. Natives of Jamaica [*].

9. Stem herbaceous, four-cornered with four decurrent wings, having hairs glandular at the tip ſcattered over it, and viſcid. Branches filiform. Leaves very ſmall, acute, having a few hairs preſſed to the ſurface ſcattered over them, obſcurely three-nerved, ciliate at the edge with glandular hairs: the uppermoſt narrower and ſublanceolate. Petiole ſhorter than the leaf, ciliate alſo with glandular hairs. Peduncles axillary, and at the forks of the branches, ſolitary, very ſhort. Calyxes hairy. Petals lanceolate. Stamens ten, longer than the petals. Capſules ſubbilobed, the ſize of Coriander ſeed.—Found by von Rohr in Cayenne [t].

10. This is a ſmall low ſhrub, with diffuſed aſcending branches, the lower ones towards their baſe rooting, four-cornered, hiſpid with frequent ferruginous hairs preſſed cloſe: branchlets axillary, oppoſite like the branches, ſhorter than the leaf. Leaves oppoſite, bluntiſh, ciliate; on the upper ſurface marked with three lines and veinleſs, having yellowiſh flatted briſtles ſcattered over them; underneath hoary, marked with three nerves, beſides thoſe that run along the edge, hiſpid with whitiſh briſtles along the nerves and midrib. Petiole ſhort, hiſpid. Peduncles commonly three or four, and ſometimes a fifth central one ſhorter than the others, hiſpid, ferruginous, one-flowered; but often one of the lateral ones two-flowered. Bractes two on each peduncle, a little above the middle, oppoſite, ſeſſile, ovate, ciliate about the edge, in other parts ſmooth, ſmall. Calyx four or five-cleft, obovate having many briſtles ſcattered over them, which are whitiſh with the tips purpliſh and glandular. Segments lanceolate, attenuated, ciliate with briſtles. Petals four or five, obovate-roundiſh, roſe-coloured, ciliate along the outer edge, with remote hairs, appearing to be terminated by a minute gland when examined with a magnifier. Stamens eight or ten,

foreign countries to be very injurious to the crop of Rie. With us it abounds only in poor paſtures, and ſome woods [a].]

Mr. Miller ſays, that the Dutch carry on a trade with the ſeeds and ſeed-veſſels of one ſpecies of this genus to Germany. They call it Semen Savadillos, and it appears very like the ſeed-veſſel of this ſort. The uſe they make of it is to kill vermin, eſpecially bugs. They boil a quantity of the ſeeds and capſules in common water, with which they waſh their wainſcot, bedſteads, &c. and it is ſaid effectually to deſtroy the inſects.

[β. Dillenius, on the authority of Dr. Richardſon, gives a variety, with ſmaller flowers, and the lower lip purple. The plant is ſaid to be larger, and very much branched, with the leaves narrower. It was found in corn fields between Wetherby and Catall in Yorkſhire, and Weſt Newton in Northumberland; but does not appear to have been obſerved ſince.

γ. Haller and other foreign writers make two ſpecies of this, the ſmooth, which is ours, and is deſcribed above, and the hairy. The illuſtrious Swiſs ſays, that the ſtem of the latter is more branched and higher, being a foot and half in height; the leaves wider, more ovate, leſs ſerrate; the leaves and bractes ſmooth, but the calyxes hirſute; the corolla paler, with a ſpotted beard or lower lip; the appendixes of the galea or upper lip, ſometimes blue, ſometimes pale; and that the difference is not owing to dryneſs only, becauſe about Gottingen and Bienne the ſmooth ſort grows in dry paſtures. He adopts the name of *Alectorolophus* from Pliny, who calls it ſo from the reſemblance of its leaves to the comb of a cock.

Scopoli adopts another name from Pliny, that of *Mimulus*; and diſtinguiſhes this from the ſmooth ſort by the calyxes being villoſe; the auricles or appendixes of the upper lip truncate, whereas in the other they are bifid; and the nectary rounded, which is acuminate in the ſmooth ſort. Theſe differences, according to him, are conſtant, and ſufficient to conſtitute a diſtinct ſpecies.

Pollich retains Linneus's name of Rhinanthus, and gives that of *Alectorolophus* to this as a trivial. According to him, the calyx is conſtantly hirſute, the flower pale yellow, the ſtem higher, the leaves wider and larger.

4. Root annual, though throwing out runners. Stem a cubit high or more, ſtraight, firm, ſquare, ſomewhat lanuginoſe. Leaves commonly oppoſite, long, narrow, pale green, with few but very large teeth, as it were jagged. Spikes of flowers heaped at the end, large, ſquare, lanuginoſe, and even ſomewhat viſcid. Flowers yellow, large [b].

Ray ſays that Columna's Trixago, which reſembles this very much, and probably is not a different ſpecies, is ſhorter, the ſtems and ſometimes the edges of the leaves are red, the flowers ſmaller and of a different colour, the cowl or upper lip being red, the lower lip white in the middle, but pale red towards the middle. He found them both on the ſides of the mountains impending over Meſſana in Sicily, in full vigour during the month of may. This ſpecies is alſo a native of Italy, the South of France and Paleſtine.

5. This plant has the appearance of the preceding, and beomes wholly black in drying. The leaves have three or four teeth on each ſide. Spike oblong, with tomentoſe bractes a little acuminate. Calyxes four-cleft, blunt, as in the third ſpecies, but tomentoſe.—Native of the Cape of Good Hope [c].

6. Root annual. Stem herbaceous, aſcending, quite ſimple, ſubtomentoſe, round, a ſpan high. Leaves oppoſite, ſeſſile, approximating, pubeſcent, nerved, deeply trifid: ſegments linear, divaricating, quite entire, acute, an inch long. Flowers from all the axils, from the bottom to the top, ſolitary, oppoſite, ſeſſile. Bracte linear, villoſe on both ſides, at the baſe of each flower, of the ſame length and form with the ſegments of the leaves. Calyx ovate, pubeſcent, inflated, membranaceous, marked with four raiſed lines, four-cleft; the ſegments linear-lanceolate, the length of the leaves. Corolla a little ſhorter than the calyx, ſomewhat villoſe on the outſide: upper lip entire, acute, ſtretched out; lower longer, with three lanceolate lobes. Filaments ſmooth. Anthers cloven at the baſe, mucronate, two-celled, open below. Germ ovate-acuminate. Style the length of the corolla, linear, ſubvilloſe. Stigma truncate. Capſule ovate, acuminate; very like that of Bartſia, but it has the calyx of Rhinanthus.—Native of Armenia [d].

7. A ſpan high. Stem upright, quite ſimple, four-cornered, hiſpid. Leaves oppoſite, ſmall. Flowers from the upper axils, ſeſſile, ſolitary, oppoſite, turned to one ſide. Calyx half-four-cleft, acute. The reſt as in the generic character [e].—Native of Ceylon.

8. Anthers rough-haired. Native of Virginia. It ſeems allied to Gerardia flava [f], and is doubtleſs a Gerardia.]

PROPAGATION AND CULTURE.

Theſe plants diſliking culture, are with difficulty kept in gardens. Being annual, they can only be propagated by ſeeds, which ſhould be ſown ſoon after they are ripe, where they are to remain, for they will not bear removing. They require a moiſt rich ſoil and a ſhady ſituation. When the plants come up, thin them and keep them clear from weeds. If the ſeeds be permitted to ſcatter, the plants will come up better than when ſown by hand; but they thrive beſt among graſs.

The common Rattle (n. 3.) is a very troubleſome weed among Graſs, inſomuch that in many water meadows, there is more of this plant than of herbage. The ſeeds ripening by the time theſe meadows are commonly mowed, the ſeeds ſcatter, and fill the ground with young plants the following ſpring. In order to deſtroy this annual weed, the graſs ſhould be cut as ſoon as the flowers appear.

When perſons buy Graſs-ſeeds, they ſhould be very careful, that none of this ſeed is mixed with it.

Leaves ovate-lanceolate oppoſite, fruits hexangular, petals ten, ſtamens twenty.

DESCRIPTIONS, *&c.*

Theſe are maritime trees, extending far and wide by their many-times rooting branches, which are frequently oppoſite. The leaves alſo in moſt of the ſpecies are oppoſite, entire and coriaceous; the younger ones revolute, and bracted after the manner of the Fig, with caducous bractes. Peduncles axillary or terminating, often dichotomous and two-flowered; in the forks jointed and two-bracted. Fruits hanging down. In R. gymnorhiza the calyx is cloven into ten or twelve parts; the petals or ſcalelets are alſo ten or twelve, folded together and as it were two-valved, each having two ſtamens within. R. Mangle has a four-cleft calyx, and four petals villoſe within and flat, each having two anthers. The fruit (which is the ſame with the diſk of the calyx) in moſt of the ſpecies, is prominent within the calycine ſegments and half ſuperior, in a few it is entirely inferior. The mode of germination in all is particular[g]. Loureiro remarks, that in all the ſpecies which he has ſeen there are twenty ſtamens or more, always placed on the calyx; whence he would have this genus removed into the claſs Icoſandria.

They are all natives of the Eaſt Indies. R. Mangle is found in the Weſt Indies alſo.

1. Leaves petioled, ſmooth. Calyxes in pairs, ſubſeſſile. Fruits very long, nodding[h]. Native of the Eaſt Indies.

2. This tree is above the middle ſize, with a lofty ſtraight trunk: the bark is thick, cloven, of a brown-red colour; with many large bowed roots ſpreading upon the cone that is covered with ſea-water. Leaves ſmooth, ſcattered, frequently heaped together at the top and petioled. Flowers ſolitary, ſcattered: calyx from ten to thirteen-parted; ſegments awl-ſhaped, erect: petals from ten to thirteen, red, nearly equal to the calyx, linear, ſoon falling off. Stamens from twenty to twenty-ſix, or double the number of the petals, and correſponding with the ſegments of the calyx. Drupe long, ſubcylindrical-ſubulate: nucleus round, ſoftiſh becoming horny[i].

Gærtner thus deſcribes the fruit.—The calyx when ripe is coriaceous, thick, divided into twelve or fourteen parts, which are linear-acuminate, and curved in: ſhell of the ſeed fleſhy-coriaceous, inverſely parabolical, regularly truncate at top, detached on all ſides, wholly immerſed in the belly of the calyx. Embryo inverted, of a greeniſh bay colour: cotyledons four, convex on one ſide, angular on the other, leafy, twiſted together, converging into a globe, graſs green: radicle detached every way from the integuments, clavate-cylindrical, obſcurely angular, very ſmooth, ſhining, from three inches to a foot and more in length, bluntiſh or acuminate.

The bark of this tree is very uſeful in dying ruſous or cheſtnut colour; which is eaſily changed into a very fine permanent black[k].

Native of the Eaſt Indies; the coaſt of Malabar, the ſtraits of Malacca, Amboyna, &c. On the ſhores to the ſouth of Cochinchina and Cambodia there are vaſt tracts of it. The fruit becomes no leſs hard than the Areca nut, and is not eatable in Cochinchina[l].

Our circumnavigators found it on the iſland of Namoka in the South Seas[m].

3. This does not exceed the height of ſeven feet. Leaves oppoſite, on ſhort petioles, of the ſame texture as in R. Mangle, but longer, and with round edges. Petals whitiſh, thick, ſtiffiſh. The flowers have a weak, but not unpleaſant ſmell. The fruit much reſembles that of R. Mangle.

Native of the Eaſt Indies, in ſalt ſhallow water[n].

4. The Mangrove tree commonly attains the height of fifty feet; the wood is white, but becomes red when macerated in water; the bark is thick and ruſt-coloured. Leaves ovate, ſlightly attenuated at the end, blunt, quite entire, ſhining, coriaceous, deep green on the upper ſurface, on the lower yelloviſh green with blackiſh dots, petioled, oppoſite, from three to ſix inches long; on the younger branches,

[g] Juſſieu. [h] Linn. zeyl. [i] Loureiro. [k] Idem. [l] Idem. [m] Forſter. [n] Ray.

 which

Digitized by Google

RHI

which have no flowers, they are about two inches aſunder, and in young trees the internodes are even ſix inches long; but on the old and flowering branches they are nearer, and very old ones are almoſt covered with leaves. Each pair of leaves, before it is unfolded, is rolled up in two oblong convoluted erect ſtipules, which ſoon fall off, leaving two ſcars on the branch, alternate with the leaves. Common peduncles axillary, ſolitary, an inch long, compreſſed, marked with a longitudinal groove, two-flowered, bifid, ſometimes three-flowered and obſcurely three-cornered: pedicels round and half an inch long; but in the fruit they are lengthened out two inches or more. The flowers are commonly without ſcent, but ſometimes they are a little ſweet. Calyx deeply four-cleft, yellowiſh. Petals four white. Anthers conſtantly eight, ſeparating elaſtically into two parts at the baſe, and hence very caducous [s]. Browne ſays, that the number of filaments varies from four to twelve, but that eight is the moſt common number.

Jacquin has given a deſcription of the fruit, and the extraordinary mode in which the ſeed germinates, but it is much too long to inſert in a general work. According to Gærtner, there is no pericarp, unleſs the belly of the calyx be admitted as ſuch, the ſeed being cloſely faſtened to it: and this is what Jacquin conſiders as the pericarp. Receptacle none, except the inner ſurface of the calyx. Seed one, ovate, gibbous at the baſe, ſomewhat rugged, brown, terminated by the ſtyle, finally burſt open at the top by the radicle growing out: cover ſingle, thick, fleſhy-coriaceous, never ſeparating from the calyx. Albumen at the bottom of the ſeed, veil-ſhaped, glandular-fleſhy, orange-coloured. Yolk (vitellus) ſubcylindrical, fibrous-fleſhy; at bottom rounded with a little head, plunged in the cavity of the albumen; at top fiſtular and united with the radicle of the embryo: theſe are the *calyptra* and *crus* of Jacquin. Embryo inverted, green, germinating within the ſeed, and burſting its integument by its radicle: cotyledons four or ſix, leafy, plaited and convoluted, converging into a ſlender ſubulate cone: radicle when mature very long, ſubulate-clavate, bay-coloured, having calloſe dots here and there ſcattered over it, ſuperior.

The fruit of this tree, ſays Browne, germinates within the cup, and grows from the top downwards, until it acquires a due degree of weight and perfection: then it falls off; and as the root is always thickeſt, and hangs loweſt, it drops in that direction, and is thus received in its natural poſition in the mud below: the leaves immediately unfold, and in a few minutes a perfect plant is ſeen, ſometimes of ten or twelve inches in length, which ſoon begins to ſhoot its roots, and puſh its growth like the parent ſtem, for the germ is frequently a foot in length before it falls, and has always two leaves at the top; but theſe are folded up, and incloſed within the cup whilſt it continues on the tree.

The Mangrove is generally found on the borders of the ſea, in whoſe waters alone it ſeems to thrive; and there only in ſuch places as have a ſoft and yielding bottom. Its larger branches frequently emit ſoft and weakly appendicles, that have the appearance of ſo many ſlender leafleſs branches, and bend always downwards: but as theſe are ſofter, and furniſhed each with a large column of a lax ſpongy pith in the centre, they grow more luxuriantly than the other parts of the tree, and reach the mud in a ſhort time, where they throw out a numberleſs ſeries of ſlender fibres, which in time become roots, to ſupply the ſtem more copiouſly with nouriſhment, whilſt they become ſo many props or limbs to the parent tree. Thus it continues to enlarge its bulk, as its weight increaſes, or its branches ſpread; theſe conſtantly throwing out new appendicles as they multiply their ſhoots, and ſo forms thoſe interwoven groves we ſo frequently meet with on the ſea ſhore in the tropical climates, which ſerve to ſtop the mould that is conſtantly waſhed down by thoſe rapid floods that come from the inland parts, and thereby in time turn what might have otherwiſe continued uſeleſs ponds or open creeks, into rich and fertile fields [r].

The quantity of moſkitoes that frequent theſe maritime foreſts make it impoſſible for an European to live or even paſs a night near them: they are inhabited by innumerable ſea birds and crabs, and the matted roots enable the ſavage to walk about the ooze and ſhallow waters to hunt for them [q].

The trunk of the Mangrove ſeldom grows to any conſiderable thickneſs, but the wood is very tough and hard, bears the water well, and is much uſed for knees and ribs in long-boats, and other ſmall-craft; for which the arches and angles of its limbs moſt naturally adapt it. Jacquin ſays, it is fit for nothing but to burn. The lower branches frequently become the ſupporters of the American oyſter, which has given riſe to the fabulous account of the growth of this ſhell-fiſh on trees, as a fruit. Piſo ſays, that a piece of the root toaſted, and applied warm to the painful wounds inflicted by the ſting of the fiſh *Nigui*, ſoon quiets the pain [r].

The bark is moſt excellent for tanning leather; it performs this operation more perfectly in ſix weeks than oak-bark will do in ten; and the leather tanned with it is the moſt firm and durable of any for ſoles. The decoction of it is a moſt powerful aſtringent [s].

According to Dampier, there are three ſorts of Mangrove trees, black, red, and white. The black is the largeſt, the body as big as an Oak, and about twenty feet high. It is hard and ſerviceable timber, but extraordinary heavy. The red grows commonly by the ſea ſide, or by rivers or creeks. The body is not ſo big as that of the black, but always grows out of many roots about the bigneſs of a man's leg, which at about ſix, eight or ten feet above the ground, join into one trunk, which ſeems to be ſupported by ſo many artificial ſtakes. The timber is hard, and good for many uſes. The inſide of the bark is red, and is uſed for tanning of leather very much all over the Weſt Indies. The white never grows ſo big as the other two, neither is it of any great uſe. Of the young trees they make handles for their oars, for it is commonly ſtraight, but not very ſtrong. Neither the black nor white grow towering up from ſtilts, as the red does, but the body grows immediately out of the ground, like other trees.

The Mangrove is a native both of the Eaſt and Weſt Indies, of the Society and Friendly iſlands, the new Hebrides and new Caledonia in the South Seas. The Spaniards call it Mangle; the French, Mangle and Paletuvier.

5. This tree agrees with the *gymnorhiza*, except that it is above three times the height of a man, and is not divided into ſo many trunks. The leaves are of the ſame form, but much ſmaller, being only four or five inches long at moſt, and on ſhorter petioles. Flowers white, axillary, three together, or ſometimes but more ſeldom two. Petals eight, acuminate. Filaments whitiſh, with red anthers. Fruit as in *R. gymnorhiza*, except that it is the breadth and thickneſs of the little finger, with a green rind when young, but when older reddiſh-blue.

Native of Malabar, in ſalt marſhes. The fruit is eaten when young and tender [t].

Gærtner conſiders this, which is the *Mangium minus* of Rumphius, and alſo the *M. digitatum* of the ſame author, (*p.* 107. *t.* 70.) as varieties of *R. gymnorhiza*, *n.* 2.

6. This is a middle-ſized tree, with twiſted ſpreading branches. Leaves quite entire, flat, ſmooth. Flowers ſubterminating, ſolitary: calyx bell-ſhaped, continuing in the ſame form, large, ten-parted, with ſharp ſpreading ſegments: petals red, oblong, emarginate, ciliate, nearly equal to the calyx. Filaments longer than the calyx, on which they are placed, with oblong ſtanding anthers. Germ oblong, ſuperior: ſtyle equal to the ſtamens. Drupe oblong, priſmatical, regularly hexagonal, ſtraight, blunt, with a co-

GENERIC CHARACTER.

* *Male.*

CAL. *Perianth* four-parted, concave, erect, obtuſe, permanent.

COR. *Petals* four, oblong, obtuſe, from erect-ſpreading, double the length of the calyx, deciduous.

Nectaries four, erect, emarginate, ſhorter than the calyx.

STAM. *Filaments* eight, awl-ſhaped, longer than the corolla. *Anthers* ſimple.

PIST. *Germs* four, oblong, acuminate. *Styles* and *Stigmas* obſolete.

PER. abortive.

* *Female.*

CAL. *Perianth* as in the male.

COR. *Petals* four, rude, erect, obtuſe, equal with the calyx, permanent.

Nectaries as in the male.

PIST. *Germs* four, oblong, acuminate, ending in ſimple ſtraight *Styles*. *Stigmas* obtuſe.

PER. *Capſules* four, horned, opening inwards.

SEEDS very many, roundiſh.

OBS. *Dahl obſerved hermaphrodite flowers with ten ſtamens and five ſtyles. This genus therefore may with the greater confidence be aſſociated with the Sedums.*

ESSENTIAL CHARACTER.

MALE. *Cal.* four-parted. *Cor.* four-petalled. *Nect.* four.

FEM. *Cal.* four-parted. *Cor.* four-petalled. *Nect.* four. *Piſt.* four. *Capſ.* four, many-ſeeded.

Leaves ovate ſerrate towards the top, ſtem upright.

[2. Rhodiola biternata.

Lour. cochinch. 627. *ed. Willd.* 770.

Leaves biternate gaſhed, ſtem twining.]

DESCRIPTIONS, &c.

1. This has a very thick fleſhy root, which when bruiſed or cut, ſends out an odour like Roſes; it has many heads, whence in the ſpring come out thick ſucculent ſtalks like thoſe of Orpine (Sedum Telephium) about nine inches long, cloſely garniſhed with thick ſucculent leaves of a gray colour, an inch long, and half an inch broad, indented on their edges towards the top, and placed alternately on every ſide the ſtalk; which is terminated by a cluſter of yellowiſh herbaceous flowers, appearing early in may. They have a very agreeable ſcent, but are not of long continuance.

[Root white. Stems numerous, ſimple, upright, leafy, cylindrical, ſmooth, hollow, from four to twelve feet high. Leaves numerous, growing without order, ovate, ovate-lanceolate, and in the younger plants lanceolate, upwards diſtantly ſerrate, towards the baſe entire, fleſhy, ſea-green, ſometimes tinged with purple. Flowers terminating, yellow. Stamens much longer than the corolla; according to Fabricius, ſix, eight or twelve, and five nectaries. Styles very ſhort, pointing outwards, permanent. It has the habit of Sedum Telephium [y]; and is ranked by many among the Sedums: but the number four is prevalent in this, whereas five prevails in the Sedums. The flowers are male and female on diſtinct plants; but ſometimes they are ſaid to be hermaphrodite, with ten ſtamens and five ſtyles: if this be frequent, the Roſewort may very properly be aſſociated with the Sedums. Linneus cultivated a female plant by itſelf during many years, and it had only ſmall unproductive ſeeds. There were none but male plants in the botanic garden at Cambridge for a long time; nor did I ever ſee any hermaphrodite flowers.

The root is ſweeteſt when dried; in this ſtate a fragrant water may be diſtilled from it. Cultivated in a garden, it loſes moſt of this ſweetneſs. Goats and ſheep are ſaid to eat the plant; but cattle and ſwine to refuſe it. The inhabitants of the Farro iſlands uſe it as a remedy for the ſcurvy. In Greenland they eat it as garden-ſtuff. A cataplaſm of the freſh roots applied to the forehead, is ſaid to relieve the head-ach, and to heal malignant ulcers [z].

Native of Lapland, Denmark and Norway, Great Britain, Auſtria, Sileſia, Switzerland, Dauphiné, Piedmont, Siberia, on mountains. With us it is found only in the northern counties of Weſtmoreland, Cumberland and Yorkſhire; in Scotland and in Wales.]

β. The roots of this are ſmaller; the ſtalks are ſmall, and not above five inches long; the leaves are ſmall, and end with a purple point; the petals are purpliſh, and the ſtamens are little longer than the petals. It flowers later. Mr. Miller ſays that he cultivated both in the ſame ſoil above thirty years, and never found either of them vary: but the differences, except the colour of the flowers, are ſuch, as may fairly be attributed to an alpine ſituation.

[2. Stem herbaceous, round, ſlender, grooved, branched. Leaflets lanceolate, tomentoſe. Flowers axillary. Male ſubumbelled, on a long common peduncle, with two oppoſite horn-ſhaped ſtipules: calyx deeply four-parted, two oppoſite ſegments of theſe twice the ſize of the others, all acute: petals four, white, turbinate, equal, ſpreading: nectaries four, upright, two of them ſhorter: filaments eight, hairy, unequal, upright, longer than the corolla. Anthers ovate, incumbent. The female has not been ſeen.

Native of Cochinchina, in ill-cultivated gardens, but not frequent [a].]

PROPAGATION AND CULTURE.

1. Plant cuttings the beginning of april, ſoon after they come out from the head, in a ſhady border; covering them cloſe down with a glaſs, and keeping them dry: they will put out roots in about ſix weeks; but the cuttings ſhould be laid in a dry room at leaſt a week before they are planted, otherwiſe they are ſubject to rot.

Or part the roots in the beginning of ſeptember, when their ſtalks begin to decay; and if the fleſhy parts are cut or broken, lay them to dry, a few days before they are planted. They require a ſhady ſituation, and a dry undunged ſoil, in which they will continue many years.

Leaves oval ſhining blunt veined with an acute reflex margin, peduncles one-flowered.

DESCRIPTIONS, *&c.*

1. This riſes with a ſhrubby ſtalk near three feet high, ſending out many irregular branches, covered with a purpliſh bark. Leaves lanceolate, an inch and half long, and half an inch broad in the middle, entire, with reflexed borders, lucid green on their upper ſurface, and ruſty-coloured underneath, placed all round the branches without order. The flowers are produced in round bunches at the ends of the branches: the corolla is funnel-ſhaped with a ſhort tube, and is cut into five obtuſe ſegments at the brim, ſpreading a little open, and of a pale roſe-colour.

[It is an irregular, diſtorted, ever-green, branched ſhrub, eighteen inches in height and more; the lower branches lying on the ground, put out fibres, and hence it may eaſily be increaſed, without the principal root, which being fixed deep in the fiſſures of rocks, is not pulled up without much difficulty. Leaves in cluſters at the ends of the branchlets, dry, coriaceous, ovate, narrowed to both ends, bent back at the edge, on ſhort petioles; underneath they are ferruginous, with innumerable little dark-coloured dots; if this be wiped off they are yellowiſh; ſometimes there are a few ciliate hairs on young leaves, eſpecially towards the baſe, but theſe ſoon diſappear. Flowers in an upright raceme at the end of every branchlet. Peduncles one-flowered, upright, dotted. Corollas nodding, of a beautiful roſe-colour with aſh-coloured or yellowiſh dots, having little or no ſcent. It varies, but not commonly, with a white flower. The two lower ſegments of the corolla are a little narrower and longer than the three others. Filaments whitiſh red, hairy at bottom, the lower ones gradually ſhorter, not exceeding the tube, inſerted into the receptacle itſelf by an attenuated toothlet: anthers oblong, erect, yellow. The ſtamens commonly fall before the corolla. Germ ſuperior, green: ſtyle nearly the length of the ſtamens: ſtigma capitate-five-cleft [b].

Native of high mountains in Switzerland, Auſtria, Savoy, Piedmont, Dauphiné. Where this and the *birſutum* terminate ligneous vegetation as we aſcend, and furniſh the ſhepherds with their only fuel. The grous are ſaid to eat it; and the white hares ſometimes gnaw the bark in hard weather; but animals do not ſeem to feed on it, except from want of other food; and it is ſuſpected of being in a ſmall degree poiſonous. The galls of ſome ſmall inſect are frequent on it.

Mr. Miller cultivated it in 1739. It flowers from may to july [c]: but ſeldom produces them with luxuriance in a garden.

2. Root tuberous-knobbed, thick, deeply bound down by rootlets ſtriking into the ground, or into the fiſſures of rocks. Trunks very ſhort above ground, twiſted and knobbed; theſe and the roots put out many ſhoots or runners, which are ſtiffly upright, two ells high at moſt, round, covered with a gray bark, which throws off yearly an aſh-coloured ſkin: the

[b] Jacquin, Haller. [c] Hort. kew.

Digitized by Google

wood is white, with a ſlender ruſſet pith. Branches frequent, ſtiffiſh, wand-like: the annual ones tenderly pubeſcent. Leaves alternate, ovate-acute, ſubcoriaceous, very ſmooth, dotted, very obſcurely crenulate on the edge, on petioles very finely pubeſcent: before they are completely unfolded they are rolled back at the edge: in cold weather they become of a duſky purple. The flowers come out before the leaves at the ends of the branchlets of the former year, from a bud that continues the branch, compoſed of ferruginous, ſubpubeſcent, concave ſcales: they nod a little, and have ſome ſmell. The calyx is only the margin of the receptacle ſlightly five-toothed. Corolla large, purple, half-five-cleft; the three upper ſegments ſcarcely wider. Stamens unequal, purpliſh: anthers purple, emitting a greeniſh-livid pollen. Germ ſuperior: ſtyle declined, longer than the ſtamens, purple: ſtigma fungus-ſhaped, twin. Capſule ripening in autumn, at the baſe of the year's ſhoots, ſolitary, convex, five-cornered, acute, faſtened by naked peduncles to an oblique rugged receptacle, five-celled, opening at top. Seeds ferruginous, irregular like ſawduſt [d].

Stem naked, proliferous, leafy at the end. Leaves petioled, oblong, naked above, dotted on both ſides in cluſters, ferruginouſly dotted underneath very cloſely. Corollas violet-coloured, wider than the leaves. Stamens ſpreading, the length of the corolla. Style blood-red. It reſembles Azalea lapponica [e].

Native of Siberia; peculiar to the ſubalpine tracts of eaſtern Aſia; it appears firſt at the jaws of the river Jeniſea, and beyond that, eſpecially from the river Uda, in the pine woods, it begins to be common, but about Baikal it is moſt abundant, and extends through the deſerts of the Mongols to China and Tibet: at the Lena it becomes more rare, and beyond that it is much lower with a more ſlender flower and narrower leaves [f].

It was introduced here in 1780, by Anthony Chamier, Eſq. [g]

3. This ſhrub, in alpine ſituations is leſs than a foot in height, in lower grounds it grows to a foot and half, ſending out abundance of decumbent branches, having their ends emerging from the moſs, ſubdivided, bearing both leaves and flowers. Trunk ſeldom the thickneſs of two or three fingers, commonly an inch thick. Leaves terminating, few, alternate, ovate, uſually ſharpiſh, attenuated to the petiole, the upper ſurface netted and very rugged, the under pale or ſubferruginous, levigated, very ſmooth, the margin quite entire and bent in, of a ſtiff conſiſtence. The flowering-buds at the ends of the laſt year's branches, are made up of gray-teſtaceous ſubtomentoſe ſcales, the outer of which are ovate, the inner oblong and whiter. Among theſe ſcales iſſue the peduncles, placed alternately at the end of the branches, ſo cloſe as to reſemble an umbel; they are commonly ſix or fewer, but ſometimes ten, upright and hairy. Flowers handſome, large, nodding. Calyx none, except the receptacle of the flower, and eſpecially of the fruit, ſlightly margined and oblique. Corolla yellow, ſpreading-bell-ſhaped, with five rounded nearly equal ſegments, the three upper ones being only a little larger than the other two, towards the tube ſtriated with livid dots, the lower ones unſpotted. Stamens unequal, bent in downwards, with oblong pale anthers. Style longer than the ſtamens, declined: ſtigma five-lobed. When the flower falls, the peduncle becomes ſtiffly upright, to bear the capſule; which is of an oblong-pentagon form, ſlightly curved, ſubtomentoſe, teſtaceous, five-valved, opening at top; valves boat-ſhaped, contracted at both edges. Seeds irregular like ſawduſt, gray.

Native of Siberia, in the higheſt mountains [h].

The younger Linneus remarks, that it reſembles the preceding ſpecies ſo much, as to be perhaps no more than a variety [i].

This plant and its effects were firſt deſcribed in 1747 by Gmelin and Steller, who mention it as uſed in Siberia for the cure of rheumatiſm. Little attention however was paid to it till the year 1779, when it was recommended by Koelpin not only in rheumatiſm and gout, but even in venereal caſes; and it is now generally employed in chronic rheumatiſm, in various parts of Europe. The leaves, which are the part directed for medicinal uſe, have a bitteriſh ſubaſtringent taſte, and, as well as the bark and young branches, manifeſt a degree of acrimony. Taken in large doſes they prove a narcotic poiſon.

Dr. Home, who tried this ſhrub unſucceſsfully in ſome caſes of acute rheumatiſm, ſays that it appears to be one of the moſt powerful ſedatives which we have, as in moſt of the trials it made the pulſe remarkably ſlow, and in one patient reduced it thirty-eight beats. In other caſes, wherein the Rhododendron has been uſed at Edinburgh, it has been productive of good effects, and accordingly it is now introduced into their pharmacopœia.

The manner of uſing the plant by the Siberians, is by putting two drams of the dried leaves in an earthen pot, with about ten ounces of boiling water, keeping it near a boiling heat for a night: this they take in the morning, and by repeating it three or four times, generally effect a cure. It is ſaid to occaſion heat, thirſt, a degree of delirium, and a peculiar ſenſation of the parts affected [k].

This medicine ſhould be taken with caution, and the patient ſhould begin with ſmall doſes, increaſing them gradually: but it is not probable that it will ever be a favourite remedy in this country.]

4. This ſhrub ſeldom riſes two feet high, and ſends out many ſhort woody branches, covered with a light brown bark. Leaves ovate-lanceolate, about half an inch long, and a quarter of an inch broad, ſitting pretty cloſe to the branches; they are entire, and have a great number of fine ferruginous hairs on their edges and under ſide. The flowers are produced in bunches at the ends of the branches. The tube of the corolla is about half an inch long: the five ſegments of the brim are obtuſe, ſpread half open, and are of a pale red colour.

[It bears great reſemblance to the firſt ſpecies, but the leaves are ſhorter, blunter and ciliate at the edges, of a brighter colour, not ruſt-coloured underneath, but having larger and fewer dots; the dots of the recent leaves are round lamellæ with a more lucid margin; they are alſo more evidently petioled. The flowers are ſmaller, of a paler roſe colour, with pale puſtules: theſe are obſerved on the calyx, corolla and germ [l].

Native of the mountains of Switzerland, Auſtria, Styria, Dauphiné. In auguſt 1779, I found it in great abundance on mount Scheidegg, in croſſing from Berne to Grindelwald.

It was cultivated here in 1739, by Mr. Miller [m].

Trials have been made on its medicinal effects, which have been found to be ſimilar to thoſe of the preceding ſpecies [n].

5. This is a ſmall ſhrub, very much branched, the extreme branches leafy. Leaves oblong, hard, on ſhort, reddiſh petioles. Peduncles one, or more, an inch long, villoſe, reddiſh brown, terminating. Calyx deeply five-cleft, of the ſame colour with the peduncle; the ſegments acute. Corolla purple, the ſegments ovate. Stamens longer than theſe. Style longer than the ſtamens [o].

Native of Auſtria, Carniola, Monte Baldo, and near Saltzburgh.

6. Trunk upright, ſhrubby, commonly the height of a man, but ſometimes only half ſo high, frequently thicker than the human arm, very much branched from the bottom irregularly; the wood white, the bark aſh-coloured. Branches round, ſcarred, with a ſmoothiſh teſtaceous bark. Leaves alternately ſcattered, coriaceous, large, quite entire, very ſmooth, becoming ferruginous underneath, ſcarcely nerved except the midrib, having a longitudinal ſtreak on the upper ſurface, of a wide-lanceolate form, more attenuated towards the thick petiole. Flowering-buds formed in

[d] Pallas. [e] Linn. ſyſt. [f] Pallas. [g] Hort. kew. [h] Pallas. [i] Suppl. [k] Woodville. [l] Haller, Scopoli. [m] Hort. kew. [n] Villars. [o] Scopoli.

Digitized by Google

autumn for the year following, and conſiſting of ferruginous, ovate-acute, concave, very ſmooth, imbricate ſcales. Flowers in a ſhort raceme at the end of the branchlets, about ten, and very handſome. Calyx minute, five-toothed, ſomewhat cartilaginous. Corolla purple, large, ſpreading, deeply five-cleft; the ſegments ovate, acute, one a little wider than the reſt. Stamens the length of the corolla, purpliſh, converging in a bow. Germ ſuperior, with a purpliſh declining ſtyle, longer than the ſtamens, and a twin ſtigma. Capſules cylindrical, grooved along the ſutures of the valves, opening at top by five or ſix linear valves, channelled within, incloſing the middle pillar, which is the continuation of the ſtyle. Seeds irregular like ſawduſt [p].

Leaves like thoſe of the Laurel (Prunus Laurocerafus) perennial, acute, on ſhort ſmooth petioles. Raceme the length of the pedicels or leaves. Pedicels alternate, naked. Calyx very minute. Corolla bell-ſhaped, the ſize of Oleander, (Nerium) purple. It bears a reſemblance to Azalea pontica; but differs in the number of ſtamens [q].

Native of the Levant and Gibraltar; alſo of Georgia, in the ſouthern ſubalpine tracts of Caucaſus, &c. where it affects wet places in Beech and Alder coppices, on rocky mountains, but not on high alps [r]. Pallas doubts whether the Gibraltar plant be the ſame with that of the Levant and Caucaſus.

Tournefort has related that the flowers of this plant were reputed to impart a noxious quality to honey; this Guldenſtadt contradicts, and imputes it to Azalea pontica [s]. Introduced in 1763. It flowers in may and june [t].

7. Root creeping among moſs, thick, woody. Trunk arboreſcent, eighteen inches high, diffuſed and procumbent, ſcarred, aſcending at the end, and there leafy and flowering. Leaves cluſtered at the ends of the branches, ovate-lanceolate, coriaceous, quite entire, rolled back at the edge, obſcurely nerved; the upper ſurface duſky green, netted and rugged, the lower covered with a very ſhort nap, of a whitiſh yellow colour. Petioles ſhort, thick, wrinkled. Flowers in an umbel-ſhaped corymb, having from ſix to nine ereſt peduncles, the length of the leaves, hairy, one-flowered. Bractes remaining from the flowering-bud, larger than in R. chryſanthum, ovate-lanceolate, ferruginous, ſubtomentoſe. No calyx, except the receptacle of the flower margined, oblique, five-notched; the two upper notches larger. Corolla nodding, very large, white or reddiſh, ſpreading bell-ſhaped, half-five-cleft; the ſegments nearly equal, a little waved, the three upper ones with livid ſpots at the baſe. Stamens for the moſt part ten, but ſometimes eight, ſeven, ſix or five, little more than half the length of the corolla, unequal, even; with ovate, two-grooved anthers; the filaments adhere to the receptacle and bottom of the corolla. Germ pyramidal, five-cornered, ſuperior, hirſute: ſtyle thick, declining in a bow, longer than the ſtamens: ſtigma headed, lobed. Capſule an oblong pentagon, blunt, ſcarcely curved, five-celled, opening at the top, ſubtomentoſe. Seeds like ſawduſt brown.

Native of the higher rocks of Caucaſus, near the perpetual ice, in the higheſt range of ſhrubby vegetation, with Myrtillus and Vitis idæa.

8. This is a very elegant underſhrub. Root woody, dry, the ſize of a quill, creeping by proſtrate runners, of a brown teſtaceous colour. Branchlets riſing, leafy, frequent. Leaves cluſtered, alternate, ſeſſile, ovate attenuated to the baſe, five-nerved, ſomewhat acute, quite entire at the edge, and ciliate with remarkable hairs. Peduncles from few only of the branchlets two or three inches long, accompanied at the baſe by ſmaller leaves, and commonly by two ſeſſile ovate leaves, two-flowered (ſeldom one or three-flowered,) very hairy. The partial peduncles have one or two lanceolate leaflets, and a nodding flower. Calyx from five foliaceous, three-nerved, ciliate leaflets, like the reſt of the leaves, two of them more approximating than the others. Corolla wheel-ſhaped, irregular, purple, with a very ſhort tube, and a deeply five-cleft border: ſegments lanceolate, pubeſcent at the edge, unequal, the three upper ones being a little ſmaller, and leſs deeply cloven, ſpotted with red at the baſe, and ſomewhat erect like a helmet; the lower ones ſpreading very much and unſpotted. Stamens from the bottom of the flower, declined, purple, unequal, the upper ones ſhort, the lower double their length, but not ſo long as the corolla; anthers ovate, twin, dark purple. Germ ſuperior, five-cornered: ſtyle as long as or longer than the corolla, declining in a bow, purple: ſtigma fungus-ſhaped, thick, three-lobed. Capſule within the leafy calyx now augmented and converging, ovate, five-cornered, five-celled. Seeds brown.—It agrees with R. Chamæciſtus in its ciliate leaves, and wheel-ſhaped flowers; but differs widely from it in the nervature and ſize of the leaves; its leafy two-flowered ſolitary peduncles; leafy calyxes; the whole form of the flower, and the manner of growth.

It was firſt diſcovered by Steller, and grows abundantly in the peninſula of Kamtſchatka and Bering's iſland, in muddy places on the mountains. It begins to flower at the end of july, and ripens its ſeeds towards the end of ſeptember [u].]

9. This riſes, in its native ſoil, fifteen or ſixteen feet high, with a ſhrubby ſtalk, ſending out a few branches towards the top. Leaves ſtiff, ſmooth, ſix inches long and two broad, of a lucid green on their upper ſide, and pale on their under, whilſt young, but afterwards changing to the colour of ruſty iron: they have ſhort thick footſtalks, and are placed without order round the branches: between theſe the buds are formed for the next year's flowers; theſe ſwell to a large ſize during the autumn and ſpring months till the beginning of june, when the flowers burſt out from their covers, forming a roundiſh ſeſſile bunch or corymb. The corolla is of a pale colour, and cut almoſt to the bottom into five blunt roundiſh ſegments, one of which is ſtudded with yellow green and purpliſh protuberancies. [The branches and leaves are of the ſame ſize and conſiſtence with the Laurel (Prunus Laurocerafus,) the latter have reticulated veins, and are bent back at the edge. The loweſt ſegment of the corolla is ſpotted [x]. Capſule oblong, rounded-pentagonal, pubeſcent, viſcid, ferruginous, five-celled, five-valved: partitions doubled, formed of the margins of the valves bent in. Receptacle columnar, fungous, five-lobed, lobes flatted a little, prominent between the cells. Seeds linear-oblong, ſomewhat chaffy, acuminate at both ends, ſmooth, fulvous or deeply ruſeſcent [y].]

Native of North America, upon rocks and in barren ſoils, where it continues flowering great part of the ſummer, and is a great ornament to the barren rocks.

[It was introduced here in 1736, by Peter Collinſon, Eſq. and flowers from june to auguſt [z].] Mr. Miller ſays, the only perſon who ſucceeded well in raiſing it, was Mr. James Gordon of Mile-end, who poſſeſſed many of the plants, which grew with him from ſeeds. He adds, that the ſhrub from which the drawing was made (about 1756) for his figures of plants, was the firſt which had flowered in England.

PROPAGATION AND CULTURE.

Theſe ſhrubs are propagated by ſeeds, but theſe are ſo very ſmall, that if they are covered deep, they will not grow. They ſhould be ſown as ſoon as poſſible after they are ripe, either in a ſhady border, or in pots filled with freſh loam, and very lightly covered with a little fine earth. Plunge the pots up to their rims in a ſhady border, and in hard froſt cover them with bell or hand-glaſſes; taking them off in mild weather. If theſe ſeeds be ſown early in autumn, the plants will come up the following ſpring. Theſe muſt be kept ſhaded from the ſun, eſpecially the firſt ſummer, and duly refreſhed with water: in the autumn following tranſplant them to a ſhady ſituation, and on a loamy

ſoil,

Digitized by Google

foil, covering the ground about their roots with moſs, to guard them from froſt in winter, and keep the ground moiſt in ſummer.

They may alſo be increaſed from ſuckers or offſets, which they produce plentifully where they grow naturally, but they ſeldom produce ſuckers in England, nor do the ſeeds come to maturity.

SPECIES.

1. Rhodora canadenſis.

Lin. ſpec. 561. *L'Herit. ſt. nov.* 141. *t.* 68.

Chamærhododendros. *Duham. ſem. app.* 10. *t.* 27. *f.* 2.

DESCRIPTION, *&c.*

It is chiefly diſtinguiſhed from the Rhododendrons by its three-petalled corolla, and appears to be generically diſtinct from them: but has nothing of the herb of Rhododendron. It has the habit rather of *Azalea*. The ſtem is upright, ſomewhat branched, round, aſh-coloured, two feet high. Leaves alternate, oblong, almoſt entire, ſcarcely nerved, with the midrib prominent underneath; the upper ſurface almoſt naked, bright green, the lower pubeſcent, glaucous, ſpreading, two inches long, one inch wide; on round petioles, flatted on one ſide, pubeſcent, eight times ſhorter than the leaf. Flowers in umbels, on ſhort pedicels, purple, the upper lip with darker ſpots.

Rhodora agrees with the foregoing genus in having the calyx inclined; the filaments villoſe at the baſe, aſcending a little at the end, inſerted into the receptacle; the anthers biperforated; the ſtyle a little declined; the capſule faſtened obliquely to the calyx; the receptacle of the ſeeds five-cornered: but the corolla is abſolutely three-parted in *Rhodora*, whereas it is bell-wheel-ſhaped, with an inclined five-parted nearly equal border in *Rhododendrum*; the ſeeds are margined all round in this, but in that they are ſcarcely augmented at each end.

Native of Newfoundland; whence it was introduced by Sir Joſeph Banks.

PROPAGATION AND CULTURE.

It is raiſed with great difficulty from ſeeds, like other ſhrubs in which they are ſo very ſmall. It may be propagated by ſlips or cuttings; and thrives beſt in a good moiſt ſandy loam *.

34. Rhus atrum.
Lin. ſpec. ed. Willd. 1486. *Forſt. prodr. n.* 142.
Leaves ſimple ovate-oblong, flowers polygamous.]

DESCRIPTIONS, *&c.*

1. The common or elm-leaved Sumach has a ſtrong woody ſtem dividing into many irregular branches, and riſes to the height of eight or ten feet; the bark is hairy, and of an herbaceous brown colour whilſt young. The leaves are compoſed of ſeven or eight pairs of leaflets terminated by an odd one: theſe leaflets are about two inches long, and half an inch wide in the middle, and are of a yellowiſh green colour. The flowers grow in looſe panicles at the end of the branches, each panicle being compoſed of ſeveral thick ſpikes of flowers ſitting cloſe to the footſtalks: they are of a whitiſh herbaceous colour, and appear in july, but are not followed by ſeeds in England.

It grows naturally in Italy, Spain, [the South of France, the Levant, about Aleppo Rama, &c.; near Algiers in Africa.—From the catalogue of the botanic garden at Oxford it appears that it was cultivated there in 1648 [b].]

The branches are uſed inſtead of Oak bark for tanning leather, and it is ſaid that Turkey leather is all tanned with this ſhrub. The leaves and ſeeds are uſed in medicine, and are eſteemed very reſtringent and ſtiptic. [The Tripoli merchants ſell the ſeeds at Aleppo; and they are in common uſe there at meals to provoke an appetite [c].]

2. This has a woody ſtem, from which are ſent out many irregular branches, generally crooked and deformed. The young branches are covered with a ſoft velvet-like down, reſembling greatly that of a young ſtag's horn both in colour and texture, whence it has vulgarly the name of the Stag's-horn tree. The leaves have ſix or ſeven pairs of leaflets, terminated by an odd one; their under ſurface and the midrib are hairy. The flowers are produced in cloſe tufts at the end of the branches in july; and are followed by ſeeds, incloſed in purple woolly ſucculent covers, ſo that the bunches are of a beautiful purple colour in autumn: the leaves alſo then change firſt to a purpliſh, and before they fall, to a feuillemort colour. This ſhrub, as well as the preceding, is uſed for tanning leather; and the roots are preſcribed in medicine, where it grows naturally; that is in almoſt every part of North America, [particularly Virginia and Carolina. It was cultivated here in 1629, as appears from the Paradiſus terreſtris of Parkinſon [d]; who ſays, that it was then only kept as a rarity and ornament to a garden or orchard.

3. This is a large tree with ſpreading branches. Leaves unequally pinnate, with from five to ſeven pairs of leaflets; theſe are parallel-nerved, ſmooth above, but ferruginous-tomentoſe underneath, an inch long, the upper ones gradually larger. Petiole below the leaflets round, ſmooth; between them, winged on each ſide. Flowers ſmall, in a compound, tomentoſe, terminating panicle. Corolla white, bell-ſhaped, longer than the calyx, ſtriated. Anthers ſeſſile, very ſmall. Styles three ſhort.

Native of China and Japan, where it flowers in ſeptember [e].

The Chineſe extract an oil from the berries by bruiſing them and boiling them in water; they uſe it as a varniſh, which is beautiful, but does not keep its poliſh ſo well as the true ſort [f].

4. This is not ſo high as the common Virginian Sumach, the branches are much more ſpreading and ſmooth, the leaflets are wider and leſs ſerrate, they are of a deeper green, and have only a hoary cloud or bloom on the under ſurface, which may be wiped off with the fingers; whereas in that they are covered with a hoary pubeſcence; the panicle is more diffuſed in this [g].

Native of North America, in woods, high glades, and old corn fields. It is like a weed in ſome parts of the country, and if a field be left a few years uncultivated, this ſhrub overruns it, from berries which are brought by birds; and when the ground comes again into tillage, the roots ſtop the plough very much. The fruit remains on the ſhrub during winter; but the leaves drop very early in autumn. It ſeldom grows above three yards high. The wood burns well, without much crackling. On cutting the ſtem, a yellow juice comes out between the bark and the wood; one or two of the outer circles are white, but the innermoſt are of a yellowiſh green: it contains a pith frequently half an inch in diameter or more, of a brown colour, and ſo looſe that it is eaſily puſhed out by a ſtick. The branches boiled with the berries afford a black ink-like tincture. The berries are eaten by children with impunity, but they are very ſour: they are red, and are made uſe of for dyeing the ſame colour [h].

It was cultivated in 1726, by James Sherard, M. D. in his garden at Eltham [i].

There are many ſpecies or perhaps varieties of *Sumach* in North America. Mr. Miller has two which ſeem to belong to this, namely his *glabrum, n.* 3. and *canadenſe, n.* 5. To the former he gives as a ſynonym the ſame which Linneus has given from Dillenius; to the latter Tournefort's name of Rhus canadenſe folio longiori utrinque glabro.]—The former, he ſays, is commonly called by the gardeners New England Sumach. The ſtem is ſtronger, and riſes higher than that of the *typhinum*; the branches ſpread more horizontally, they are not quite ſo downy, and the down is of a browniſh colour; the leaves are compoſed of many more pairs of leaflets, and they are ſmooth on both ſides: the flowers are diſpoſed in looſe panicles, and are of an herbaceous colour.

R. canadenſe has ſmooth branches of a purple colour, covered with a gray pounce. The leaves are compoſed of ſeven or eight pairs of leaflets, which are four inches and a half long, and one inch broad in the middle, terminating in acute points, and a little ſerrate; they are of a lucid green on their upper ſurface, but hoary on their under, and are ſmooth. Panicle large, compoſed of ſeveral ſmaller, each on ſeparate footſtalks, the whole covered with a gray pounce: the flowers are of a deep red colour. It grows natu-

[b] Hort. kew. [c] Rauwolff. [d] Hort. kew. [e] Loureiro and Thunberg. [f] Loureiro. [g] Dillenius. [h] Kalm. [i] Hort. kew.

Digitized by Google

turally in Canada, Maryland, and ſeveral other parts of North America.

5. This riſes commonly to the height of ſeven or eight feet, and divides into many irregular branches, which are ſmooth, of a purple colour, and pounced over with a grayiſh powder; as are alſo the petioles, which are of a purpliſh colour. The leaves have ſeven or eight pairs of lobes, not always exactly oppoſite; they are three or four inches long, and almoſt an inch broad in the middle; above they are of a dark green, underneath hoary but ſmooth. Flowers of a bright red colour, in very cloſe thick large panicles; appearing in july and auguſt, and continuing till autumn.

Native of South Carolina, whence it was brought by Mr. Cateſby.

[Introduced in 1726 [k].

6. Trunk ſtraight. Leaflets four or five pairs, ſometimes more, the upper ſurface green and ſmooth, the lower paler and pubeſcent, entire about the edge or ſometimes ſlightly ſinuate, with oblique ſuperficial veins, and the midrib inclining to the inner ſide, except in the odd leaflet which it divides into equal parts. Petioles oblong, purple. From the baſe of theſe come out the peduncles, which are green, and bear many flowers in a racemed ſpike; theſe are ſmall and herbaceous [l]. Fruit a juiceleſs drupe, ſlightly compreſſed, or as Gærtner expreſſes it, turgidly lenticular, ovate or round-rhomboid, with the top acuminate, oblique, excentrical: rind thick, on the outſide highly poliſhed and ſhining, within of a fibrous and fungous ſubſtance, or at firſt pulpy but not ſucculent, becoming dry when ripe, with a fibrous net, in which the ſtone lies; ſhell bony, tranſverſely elliptic, obſcurely wrinkled, thickiſh, of a pale teſtaceous colour without; in that, its figure and poliſh reſembling the fruit of Job's tears (Coix Lacryma Jobi). Seed obliquely elliptic, pale, faſtened by an umbilical chord, which aſcends from the bottom of the ſhell to the top of the ſeed [m].

According to Cutler, the bloſſoms are whitiſh; the panicles open; the fruit yellowiſh, ſmall and pear-ſhaped. It is common in ſwamps in North America, whence it is called Swamp-Sumach, and flowers in june.

It flowers here in july, and was cultivated in the botanic garden at Cheſſea in 1713 [n].] Mr. Miller ſays, that he received ſeeds and plants of it from Virginia, Penſylvania, New England and Carolina; and that it grows alſo in Japan.

[The milky juice ſtains linen a dark brown. The whole ſhrub is, in a high degree, poiſonous; and the poiſon is communicated by touching or ſmelling any part of it. In forty-eight hours inflammation appears on the ſkin, in large blotches, principally on the extremities, and on the glandulous parts of the body: ſoon after, ſmall puſtules riſe in the inflamed parts, and fill with watery matter, attended with burning and itching. In two or three days the eruptions ſuppurate; after which the inflammation ſubſides, and the ulcers heal in a ſhort time. It operates however ſomewhat differently in different conſtitutions; and ſome are incapable of being poiſoned with it at all. Perſons of irritable habits are moſt liable to receive it.

The leaves of ſome of our Poiſon-wood trees are entirely ſimilar to Kæmpfer's figure of the true Japan Varniſh tree.

The Abbé Sauvages ſtained linen black with the juice of *R. Vernix*, which it retained after a great number of waſhings in lye. The Abbé Mazeas made trial of *R. Toxicodendron*. The inſtant, he ſays, the cloth was expoſed to the ſun, it became the fineſt black he had ever ſeen [o].

Kalm gives much the ſame account of the American Poiſon Tree or Swamp Sumach. An inciſion being made, a whitiſh-yellow juice, which has a nauſeous ſmell, comes out between the bark and the wood: it is noxious to ſome perſons, but does not in the leaſt affect others. On himſelf it had no effect, except once, in a hot day, when being in ſome perſpiration he cut a branch, and carried it in his hand for half an hour, ſmelling at it now and then. It produced a violent itching in his eyelids and the parts thereabouts, during a week, his eyes were very red, and the eyelids very ſtiff: but the diſorder went off by waſhing the parts in very cold water.

Thunberg affirms that the very beſt Japan varniſh is prepared from the *Rhus Vernix*, which grows in great abundance in many parts of that country, and is likewiſe cultivated in ſeveral places, on account of the great advantage derived from it. This varniſh, which oozes out of the tree on its being wounded, is procured from ſtems that are three years old, and is received in ſome proper veſſel. When firſt caught, it is of a lightiſh colour, and of the conſiſtence of cream; but grows thicker and black on being expoſed to the air. It is ſo tranſparent, that when laid, pure and unmixed, upon boxes or furniture, every vein of the wood may be clearly ſeen. For the moſt part a dark ground is ſpread underneath it, which cauſes it to reflect, like a mirror; and for this purpoſe recourſe is frequently had to the fine ſludge, which is caught in the trough under a grind-ſtone, or to ground charcoal: occaſionally a red ſubſtance is mixed with the varniſh, and ſometimes leaf-gold ground very fine. This varniſh hardens very much, but will not endure any blows, cracking and flying almoſt like glaſs; though it can ſtand boiling water without receiving any damage. With this the Japoneſe varniſh over the poſts of their doors and windows, their drawers, cheſts, boxes, ſcymitars, fans, tea-cups, ſoup-diſhes, their portable ſtools, and moſt articles of houſhold furniture, which are made of wood [p]. It far exceeds the Chineſe and Siameſe varniſh; and the beſt is collected about the town of Jaſſino. It is cleared from impurities, by wringing it through very fine thin paper; then about a hundredth part of an oil called Toi, which is expreſſed from the fruit of Bignonia tomentoſa is added to it; and being put into wooden veſſels, either alone, or mixed with native Cinnabar, or ſome black ſubſtance, it is ſold all over Japan. The expreſſed oil of the ſeed ſerves for candles [q].]

Mr. Miller thus deſcribes the North American Sumach or Poiſon Aſh. Where it grows naturally, this tree riſes with a ſtrong woody ſtalk to the height of twenty feet or more; but in England it is ſeldom more than five or ſix feet high. The trunk is covered with a light brown bark inclining to gray. The leaves have only two or three pairs of leaflets, varying greatly in ſhape, but for the moſt part lanceolate, three or four inches long, and an inch and half broad in the middle, ſometimes rounded at the baſe, but always acute at the end; their upper ſurface is ſmooth, and of a pale lucid green, but their under ſide is pale and a little hairy. The petioles change to a bright purple, eſpecially towards the end of ſummer, and in autumn the leaves are of a beautiful purple colour before they fall off. The male flowers are produced in looſe panicles from the axils; they are ſmall and of an herbaceous white colour; the petals are roundiſh. The female flowers are on a ſeparate tree, in looſe panicles, ſhaped like the males, but ſomewhat larger, and have in their centre a rounding germ, ſupporting three very ſhort ſtyles, crowned with globular ſtigmas. The berry is variable in ſhape, being almoſt oval, or ſhaped like a ſmall Pear; but the moſt general form is roundiſh, with a protuberance almoſt like the Cicer. In warm ſeaſons the female plants produce fruit; but it does not ripen here.

This is undoubtedly Kæmpfer's *Sitz*, or true Varniſh tree, with a walnut leaf, and a fruit in a raceme, like Cicer. The dried ſpecimens alſo brought from Japan agree with the American Poiſon Tree; and the milky juice of both have the ſame quality of ſtaining.

7. [This is certainly diſtinct from the preceding, to which it is allied, but differs from it particularly in the ſize of the leaves. In this ſpecies theſe are ſomewhat rigid, ſhining on both ſides, very ſeldom equal on both margins. In Rh. Vernix the leaves are of an

[p] Travels, vol. 4. p. 62. [q] Fl. japon. 121.

Digitized by Google

opaque green. The fruit in this ſpecies is the ſize of a Cherry, and not white: in that it is only the ſize of a Pea, and white.

Native of Japan and China[x]. Introduced in 1773, by John Blake, Eſq. It flowers in june[u].

The oil of the ſeeds expreſſed whilſt warm, acquires the conſiſtence of ſuet, and ſerves for making candles. The trunk yields a varniſh, but in ſo ſmall a quantity as not to be worth collecting[t].

Oſbeck informs us that the Chineſe call the Rh. javanicum *Tay-ſha*, and the Rh. Chinenſe, by which I ſuppoſe he means this ſpecies, *Monkhi*.

The true Chineſe Varniſh or Lacker Tree, is named in China *Sat Shu*, and not *U Tong Shu*. In collecting the varniſh, they make an inciſion in the bark, and inſert a tube for the juice to run into a little pot; which is taken in every morning before ſun-riſe. The juice bliſters the ſkin[u].]

Mr. Miller's Toxicodendron altiſſimum, to which he puts the ſynonym of Faſi no ki from Kæmpfer, grows to a large ſize, ſending out many branches on every ſide, with very long pinnate leaves, having fifteen or ſixteen pairs of ſeſſile leaflets. He raiſed it from ſeeds ſent him from China; theſe ſeeds were pretty much like thoſe of the Beech tree, but ſmaller, being thick on one ſide and narrow on the other, in ſhape of a wedge.

[8. Obſerved near Macao. Deſcribed by Chevalier Murray in the Gottingen Commentaries.]

9. This ſeldom riſes more than four or five feet high, dividing into many ſpreading branches, which are ſmooth, of a light brown colour, and pretty cloſely furniſhed with pinnate leaves; theſe have four or five pairs of narrow leaflets, which are entire, two inches long and half an inch broad, ending in acute points; they are of a light green on both ſides, and in autumn change to purple: the petiole has on each ſide a winged or leafy border, running from one pair of leaflets to another, ending in joints at each pair. The flowers are produced in looſe panicles at the end of the branches; they are of a yellowiſh herbaceous colour, and appear in july, but the ſeeds do not ripen in England.

[The fruit, which is called a Berry, by Linneus, is a ſmall Drupe, of a rhomb-globular figure, blood-red, pubeſcent. Rind thin, becoming looſe by age. Shell very hard, teſtaceous. Seed kidney-ſhaped, pale; with a ſetaceous, brown umbilical chord. Cotyledons oblong, yellowiſh. Radicle bent in[x].

Native of North America. Cultivated here in 1697, by the Dutcheſs of Beaufort[y].

10. 11. Natives of the Cape of Good Hope.

12. This tree ſeldom riſes to more than twenty-five or thirty-five feet, and is very ſpreading towards the top. It is ſurrounded with round pinnate leaves, which have ſeldom above five leaflets on every rib; and the flowers, which grow in cluſters, are ſucceeded by ſo many reddiſh ſucculent capſules. It yields a great quantity of a gummy-reſin, which, when pure, is of a yellow colour, and after a ſhort time, acquires a hard brittle conſiſtence. It is daily uſed in ſtrengthening plaiſters, for which it is deſervedly much recommended. It is of a warm diſcutient nature, and may be uſed in all ſwellings ariſing from colds, &c. both externally and internally. The gum diſſolved in water is an eaſy purgative, and thought to be an extraordinary diuretic.

Native of America. In Jamaica it is frequent enough, and the hogs are ſaid to have recourſe to it when wounded in the woods[z].

13. Native of the Cape of Good Hope.

14. This tree is very much branched, and has ſtout floriferous thorns: the bark is gray. Leaves alternate, perennial, ſmooth, except the younger ones, which are ſomewhat villoſe: leaflets three to five: petiole winged, almoſt the length of the leaves. Flowers dioecous. Segments of the calyx ovoid. Petals ſpreading, ovate, pale yellow. Berry roundiſh, with three tubercles at the top, red when ripe, ſubacid, and not unpleaſant to the taſte. The bark dyes red, and is fit for tanning leather.

Native of Barbary, near Arzeau, on uncultivated hills[a].

15. 16. Natives of the Cape of Good Hope.]

17. This has a low ſhrubby ſtalk, which ſeldom riſes more than three feet high, ſending out ſhoots near the bottom, which trail upon the ground, putting out roots from their joints, whereby it multiplies and ſpreads greatly. If it be near a wall, the fibres will ſtrike into the joints, and ſupport the ſtalks when ſevered from the root. When it is thus ſupported, the ſtalks become more woody, and riſe much higher, than when it trails on the ground. The petioles are near a foot long: the three leaflets are ovate-cordate, five inches long, three inches and a half broad, each on a ſhort petiole; the two ſide ones oblique to the petiole; but the middle one equal; they have many tranſverſe veins running from the midrib to the borders. The flowers come out from the ſide of the ſtalk in looſe panicles; they are ſmall and of an herbaceous colour, male and female on diſtinct trees: the latter are ſucceeded by roundiſh, channelled, ſmooth berries, of a gray colour, incloſing one or two ſeeds. It grows naturally in many parts of North America, and flowers in july.

[Having in common with Ivy, the quality of not riſing without the ſupport of a wall, tree or hedge, it is called in ſome parts of America *creeping Ivy*. It will climb to the top of high trees in woods, the branches every where throwing out fibres that penetrate the trunk. When the ſtem is cut, it emits a pale brown ſap of a diſagreeable ſcent; and ſo ſharp that letters or marks made upon linen with it cannot be got out again, but grow blacker, the more it is waſhed.

Like Rhus Vernix it is poiſonous to ſome perſons, but in a leſs degree. Kalm relates, that of two ſiſters, one could manage the tree without being affected by its venom, whilſt the other felt its exhalations as ſoon as ſhe came within a yard of it, or even when ſhe ſtood to windward of it, at a greater diſtance; that it had not the leaſt effect upon him, though he had made many experiments upon himſelf, and once the juice ſquirted into his eye; but that on another perſon's hand, which he had covered very thick with it, the ſkin, a few hours after, became as hard as a piece of tanned leather, and peeled off afterwards in ſcales[b].

β. Trunk ſtraight and ſtout, with a browniſh aſh-coloured bark. Leaves ſmooth, veined, bright green above, ſomewhat paler underneath, pendulous and ſomewhat bent back: in the male plant the leaves are rather wider and longer, and are drawn more to a point; in the female they are ſhorter and blunter, and the petioles are reddiſh, whereas in the other they are green. Flowers axillary, in racemes; the males larger, whitiſh yellow; the females ſmaller, herbaceous, on the germ inſtead of the ſtyle there are two, ſometimes three black dots. Fruits round, the ſize and form of Coriander ſeeds, ſtreaked with five lines, remaining on the tree till new flowers come out; when the outer rind comes off, and a cretaceous ſubſtance comes into view, in which an aſh-coloured, hard, horny ſeed is involved, ſlightly divided on the upper part, and in a manner kidney-ſhaped.

The corolla is ſometimes divided only into four parts to the baſe; in the male the parts do not fall ſeparate; but in the female they are quite diſtinct. The former have a ſweet ſcent, like Lily of the valley; but the latter have no ſmell.

It differs from the next ſpecies, which is a leſs robuſt plant, with a trunk not ſo ſtout, the bark dotted and aſh-coloured: from that and from the root itſelf runners and ſuckers come out, and frequently rooting fibres, as in Ivy: the leaves alſo are much wider, leſs ſmooth, having a ſlender lanugo underneath, and the petioles are much longer than in this ſpecies. The leaves alſo in that are commonly ſinuated here and there; and the fruit is larger.

[x] Linn. mant. [u] Hort. kew. [t] Thunberg. [u] Blake, M.S. [x] Gærtner. [y] Hor. kew. [z] Browne.

[a] Deſfontaines. [b] Travels, 1. 177. engl. edit.

a. Differs

R H U

α. Differs no otherwiſe from this than in having more ſtems and ſuckers from the ſame root, and the branches lying over each other and twiſted together [c].

It was cultivated in 1727, by James Sherard, M.D.[d]]

18. The ſtalks of this ſort riſe higher than thoſe of the preceding; the branches are ſlender but woody, and have a brown bark. Leaves on pretty long petioles: leaflets oval, two inches long, one inch and a half broad, indented angularly, and hoary on their under ſide. The male flowers, which are produced on ſeparate plants from the fruit, come out from the ſide of the ſtalks in cloſe ſhort ſpikes, and are of an herbaceous colour. The females are produced in looſe panicles, agree in ſhape and colour with the males, but are larger, and have a roundiſh germ ſupporting three very ſhort ſtyles.

Native of many parts of North America.

[It appears from Parkinſon that it was cultivated here in 1640 [e]. It was one of the rare trees and ſhrubs that adorned Biſhop Compton's garden at Fulham [f].

19. Native of Carolina, where it was found by Mr. John Bartram. Introduced in 1772. It flowers in may.

20. Native of North America. Cultivated in 1759, by Mr. Miller. It flowers in may [g].

21. 22. 23. Native of the Cape of Good Hope, where they were obſerved by Thunberg.

24. Leaflets ſmall and very finely divided, like the leaves of Myrica quercifolia.—Native of the Cape [h].]

25. This riſes with a woody ſtalk to the height of ſeven or eight feet, covered with a brown bark, and having many irregular branches. Leaves on long petioles. Leaflets angular, near two inches long, and one inch broad, dark green above, downy underneath. The flowers comes out in ſlender bunches from the ſide of the branches; they are of a whitiſh herbaceous colour, and ſoon fall away.

Native of the Cape of Good Hope. [It was cultivated in 1694, by Mr. Jacob Bobart [i].

26. This is eaſily diſtinguiſhed from the other ſpecies by the hoary down on the ſtem and leaves, but it often puts off this down, and becomes only ſubvilloſe [k].]

It has a ſtrong woody ſtalk ten or twelve feet high, covered with a gray bark, with many ſmooth branches on every ſide. Leaves upon pretty long footſtalks. Leaflets about an inch long, and three quarters of an inch broad, of a lucid green above, but hoary underneath. Flowers axillary in ſmall panicles, of an herbaceous colour, appearing in july.

Native of the Cape of Good Hope. [Cultivated in 1714 [l], in the botanic garden at Chelſea.

27. Native of the Cape of Good Hope, where it was found by Thunberg [m].

28. The whole of this plant is ſmooth. The branches are ſpreading. The leaflets an inch long, the ſide ones ſmaller, paler underneath, mucronate, veined. Raceme terminating, ſuperdecompound, ſpreading. Flowers ſmall. Allied to R. anguſtifolium [n].

Leaflets mucronate. Panicle ſubterminating, ſhorter than the leaves. Peduncles long, capillary. R. lanceum of the ſupplement and Thunberg's prodromus ſeems not to be different from this [o].

Native of the Cape of Good Hope, where it was obſerved by Maſſon, and introduced in 1774 [p].]

29. This riſes with a woody ſtalk ſeven or eight feet high, dividing into ſeveral irregular branches, covered with a dark brown bark. Leaves on pretty long footſtalks. Leaflets two inches long, and half an inch broad in the middle, ending in acute points, lucid green above, but downy underneath. The flowers are produced in ſmall looſe bunches from the ſide of the branches; they are ſmall and herbaceous.

Native of the Cape of Good Hope. [Cultivated in 1714 [q], in the Apothecaries botanic garden at Chelſea.

30. Branches ſmooth. Leaves on very ſhort petioles. Leaflets very narrow, an inch and half long, mucronate, ſmooth above, ſcored with a line along the middle, having a longitudinal groove underneath from the revolute margins of the leaves. Panicles terminating and axillary. Linneus does not ſeem to have diſtinguiſhed this from the preceding, but they are evidently different. This was remarked at the Cape by Bulow [r].

31. This reſembles the next ſucceeding ſpecies, but the leaflets are lanceolate, leſs lucid, even on both ſides. Panicle long and very ſlender [s].

Native of the Cape of Good Hope, and cultivated by Mr. Miller in 1758 [t]. Perhaps it may be his R. africanum, n. 11.]

32. This riſes with a woody ſtalk like the villoſum, dividing into many branches, covered with a brown bark. Leaflets of a lucid green.

Native of the Cape of Good Hope. [Cultivated in 1697, by the Dutcheſs of Beaufort. It flowers in july and auguſt [u].]

Mr. Miller (1759) ſays, that he had then poſſeſſed ſome of the plants almoſt forty years, but they had not flowered.

33. This riſes with an irregular ſhrubby ſtalk to the height of ten or twelve feet, ſending out many ſpreading branches covered with a ſmooth brown bark, garniſhed with ſingle, obovate leaves about two inches long, and of the ſame breadth, rounded at their points, and ſtand upon long footſtalks; they are ſmooth, ſtiff, and of a lucid green, having a ſtrong midrib, whence ſeveral tranſverſe veins run towards the border. The flowers come out at the end of the branches upon long hair-like footſtalks, which divide, and branch into large hair-like bunches of a purpliſh colour; they are ſmall, white, and compoſed of five ſmall oval petals, which ſpread open. They appear in july, but are not ſucceeded by ſeeds in England. The root is uſed for dyeing: the leaves and young branches dye black: and the bark is uſed for tanning leather.

[The bractes of the panicle are filiform, hairy, and longer than the pedicels. Berries ſmooth, reſembling half the fruit of Shepherd's Purſe (Thlaſpi Burſa Paſtoris).

Native of the South of France, Spain, Italy, Auſtria, Carniola, Hungary, Bohemia, Switzerland, the Levant, and Siberia. It was cultivated in 1656, by Mr. John Tradeſcant, junior [x].

Dr. Smith found this ſhrub cultivated for tanning leather near Valcimara in the Apennines: it is called there *Scotino* [y]; which is evidently from Pliny's Cotinus. Gerarde ſays, "divers would have it named "*Scotinus*, which name is not found in any of the old "writers." He adds, "that the leaves of Venice or "ſilken Sumach are ſold in the markets of Spain and "Italy for great ſums of money unto thoſe that dreſs "Spaniſh ſkins, for which purpoſe they are very ex-"cellent." The French call it *Fuſtet*.

34. Native of New Caledonia [z].

General Obſervations.

This genus conſiſts of trees and ſhrubs: the flowers are in panicles or cloſe racemes, in ſome hermaphrodite; in others (5. 14. 17. 18.) male and female on ſeparate plants; in the two laſt polygamous, having males mixed with the hermaphrodites. From this diſtinction of the ſexes, Mr. Miller has divided the genus into *Rhus* having hermaphrodite flowers, and *Toxicodendron* having dioecous flowers. Tournefort had made the ſame diviſion before, but on different principles: *Rhus* with unequally pinnate leaves, and a villoſe berry with a globular nucleus; *Toxicodendron* with ternate leaves, a ſtriated berry and compreſſed nucleus. In *Cotinus* the leaves are ſimple, and the berry more compreſſed.

Sumach is an Arabic word. *Toxicodendron* is greek, and ſignifies *Poiſon-wood*.

PROPAGATION AND CULTURE.

1. 2. 4. 5. 9. Theſe are hardy plants, and will thrive in the open air in England. The firſt and fifth ſorts not being quite ſo hardy as the others, muſt have a better ſituation, otherwiſe their branches will be injured by ſevere froſt in the winter; they are eaſily propagated by ſeeds, obtained from the countries where they grow, if theſe be ſown in autumn, the plants will come up the following ſpring; but if ſown in the ſpring, they ſeldom come up till the next ſpring; they may be either ſown in pots, or the full ground. If they are ſown in pots in autumn, the pots ſhould be placed under a common frame in winter, where the ſeeds may be protected from hard froſt, and, if in the ſpring the pots are plunged into a very moderate hot-bed, the plants will ſoon riſe, and have thereby more time to get ſtrength before winter. When the plants come up, they muſt have a large ſhare of air, and ſhould be gradually hardened to bear the open air, into which they ſhould be removed as ſoon as the weather is favourable, placing them where they may have the morning ſun, and keeping them clean from weeds; in dry weather, if they are ſupplied with water, it will greatly promote their growth; but towards autumn it will be proper to ſtint their growth by keeping them dry, that the extremity of their ſhoots may harden; for if they are replete with moiſture, the early froſts in autumn will pinch them, which will ſometimes cauſe their ſhoots to decay almoſt to the bottom, if the plants are fully expoſed. If the pots are put under a common frame again in autumn, it will ſecure the plants from injury, for while they are young, and the upper part of the ſhoots are ſoft, they will be in danger of ſuffering if the winter proves very ſevere; but in mild weather they muſt always enjoy the open air, therefore ſhould never be covered but in froſt.

The ſpring following, juſt before the plants begin to ſhoot, they ſhould be ſhaken out of the pots, and carefully ſeparated, ſo as not to tear the roots, and then tranſplanted into a nurſery in rows three feet aſunder, and about one foot diſtance in the rows. In this nurſery they may ſtand two years to get ſtrength, and then may be tranſplanted where they are to remain.

The ſeeds which are ſown in the full ground, may be covered the firſt winter with ſome old tanner's bark to keep out the froſt, and in the ſpring it may be drawn off again after the danger of the hard froſt is over; and when the plants come up, they muſt be kept clean from weeds, which is all the care they will require the firſt ſummer; but as the plants in the full ground are apt to grow luxuriant, and continue growing late in autumn, they ſhould be covered to ſcreen them from the early froſt, which will otherwiſe kill their tops, and this often occaſions them to die down a conſiderable length, and frequently almoſt to the ground in hard winters. In the ſpring following the plants may be taken up carefully, and tranſplanted into a nurſery at the ſame diſtance as before directed.

This method of propagating the plants from ſeeds is ſeldom practiſed after a perſon is once poſſeſſed of the plants, for they are very ſubject to ſend up a great number of ſuckers from their roots, whereby they are eaſily propagated. The ſuckers of all the ſorts may be taken up and planted in a nurſery for a year or two to get ſtrength, and then may be planted where they are to remain.

Theſe ſhrubs are generally planted in plantations of flowering ſhrubs in large gardens, where they make a fine variety in autumn, eſpecially the ſecond, fourth, and fifth ſorts, with their large purple, or red panicles, which have a good effect; but where theſe are planted, their ſuckers muſt be every year taken off, otherwiſe they will grow up to a thicket and deſtroy the neighbouring plants.

The 6th, 17th, 18th, 19th, 20th ſorts propagate in plenty by their creeping ſtalks and roots, or by laying down their branches, which will put out roots in one year, and may then be taken off and tranſplanted, either in the places where they are to remain, or in a nurſery, to grow two or three years to get ſtrength before they are planted out for good; they are alſo propagated by ſeeds, which ſhould be ſown on a bed of light earth, and when the plants come up they muſt be kept clean from weeds the following ſummer; and before the froſt comes on in autumn, the bed ſhould be hooped over, that the plants may be covered with mats, for otherwiſe the early froſts will kill their tops, which frequently cauſes their ſtalks to decay to the ground; for as the plants are tender, and generally ſhoot late the firſt year, they are in much greater danger than when they get more ſtrength. In ſpring the plants may be tranſplanted into nurſery-beds to grow a year or two, and may then be tranſplanted for good.

Theſe plants are preſerved by the curious in botany for the ſake of variety, but as there is little beauty in them, there are not many of the ſorts cultivated in England. The wood of theſe trees, when burnt, emits a noxious fume, which will ſuffocate animals when they are ſhut up in a room where it is burnt: an inſtance of this is mentioned in the Philoſophical Tranſactions by Dr. William Sherard, which was communicated to him in a letter from New England by Mr. Moore, in which he mentions ſome people who had cut ſome of this wood for fuel, which they were burning, and in a ſhort time they loſt the uſe of the limbs, and became ſtupid; ſo that if a neighbour had not accidentally opened the door, and ſeen them in that condition, it is generally believed they would ſoon have periſhed.

10. 11. 13. 15. 16. 21. 22. 23. 24. 25. 26. 27, 28, 29. 30. 31. 32. All theſe African ſorts being too tender to live through the winter in the open air in England, are planted in pots or tubs, and houſed in autumn, and during the winter they muſt be treated in the ſame way as other hardy green-houſe plants. They all retain their leaves through the year, and make a good variety when intermixed with other plants in the green-houſe in winter. They may be propagated by cuttings, which ſhould be planted in pots filled with loamy earth the beginning of april, and plunged into a very moderate hot-bed, covering them cloſe with hand or bell-glaſſes, and ſcreening them from the ſun in the heat of the day. The cuttings ſhould be now and then refreſhed with water, but it ſhould not be given in too great a quantity. With this management they will put out roots in about two months, and when they begin to ſhoot, they ſhould have air admitted to them, and be gradually hardened to bear the open air, into which they muſt be removed, placing them in a ſheltered ſituation; and when the cuttings have filled the pots with their roots, they ſhould be ſhaken out of the pots, and parted carefully, planting each into a ſeparate ſmall pot, placing them in the ſhade till they have taken new root, when they may be intermixed with other exotic plants in a ſheltered ſituation for the ſummer, and in autumn removed into the green-houſe.

33. Venice Sumach is propagated by layers in autumn; by the autumn following theſe will have taken root, when they may be taken off, and tranſplanted into a nurſery: there let them grow a year or two to acquire ſtrength, and then plant them out where they are to remain. This ſhrub is ſo hardy, as not to be injured by froſt in England, where it is cultivated for ornamental plantations.

Prickles ſubaxillary, fruit prickly in racemes.

DESCRIPTIONS, *&c.*

[This genus conſiſts of well known ſhrubs, ſome of which are prickly others not; hence Tournefort and Miller have divided it, under the names of Ribes and Groſſularia. Juſſieu and Gærtner prefer the latter name for the whole genus. In the prickly diviſion the prickles are commonly ſimple, but ſometimes they are parted. The leaves are alternate, with the petiole widened at the baſe and half embracing, in the unarmed diviſion ciliate, or ſometimes even ſpinuloſe. Peduncles axillary, or burſting from the gems; in the prickly ſpecies from one to three-flowered, in the unarmed many-flowered in racemes. The flowers have each one bractæ: in R. alpinum they are dioecous. The fruit is an eſculent berry. The periſperm in R. rubrum is horny, as in the Ranunculaceæ, not farinaceous. Is that the caſe in the other ſpecies[a]?

1. Branches ſmooth. Leaves on longiſh petioles, doubly ſerrate, ſubpubeſcent. Racemes ſimple, nodding, when in fruit pendulous. Bractæ ovate, ſmall, ſhorter than the pedicels. Corolla yellowiſh green, with obcordate petals. Berries acid, ſhining[b].

Native of Europe, chiefly in the northern parts, in hedges and woods; flowering in may. Undoubtedly wild in the northern counties of England, Yorkſhire, Durham and Weſtmoreland, as on the banks of the Tees, &c. and in Scotland, in the iſland of Iſla: but in other parts of our iſland it occurs only in hedges accidentally.

The fruit of the Currant is generally acceptable, either as nature preſents it, or made into jelly. If equal weights of picked Currants and pure ſugar are put over the fire, the liquor that ſeparates ſpontaneouſly is a moſt agreeable jelly. The juice is a pleaſant acid in punch[c]; and was a common beverage, in the coffee-houſes at Paris, when I was there in the year 1763.

This fruit being conſidered as alimentary, was not received into the Materia Medica here, till the laſt edition of the London Pharmacopœia in 1788.

The medicinal qualities of red Currants appear to be ſimilar to thoſe of other ſubacid fruits, which are eſteemed to be moderately refrigerant, antiſeptic, attenuant and aperient. They may be uſed with conſiderable advantage to allay thirſt in moſt febrile complaints; to leſſen an increaſed ſecretion of bile, and to correct a putrid and ſcorbutic ſtate of the fluids, eſpecially in ſanguine temperaments: but in conſtitutions of a contrary kind, they are apt to occaſion flatulency and indigeſtion[d].

This ſhrub is very apt to be infeſted by the *Aphis Ribes*, and then the green leaves become red, pitted and puckered[e].]

The Currant has been long cultivated in our gardens and greatly improved. At preſent we have the following varieties. The common ſort with ſmall red fruit; the ſame with white fruit; another with pale fruit, commonly called the Champaign Currant, differing only in being of a pale red or fleſh-colour; the taſte is the ſame, but the colour makes a variety for the table. But ſince the white and red Dutch Currants have been introduced and become common, the old ſorts have been almoſt baniſhed, and are rarely to be found in the Engliſh gardens.

[β. Sweet Currant was obſerved by Bobart in Lord Ferrers's garden at Stanton, brought out of the neighbouring woods. Dr. Richardſon alſo found it near Settle in Yorkſhire.

γ. Small-fruited Currant was remarked by Metret in many parts of Lancaſhire, alſo at Wimbleton in Surrey; where Mr. James Sherard found it ſince plentifully[f]. But this could only be the common garden Red Currant in a wild ſtate, carried there probably by birds.]

A variety with blotched leaves is kept in ſome plantations; but as the virriegation is apt to go off when the plant is vigorous, it ſcarcely deſerves notice.

[This wholeſome and agreeable fruit does not ſeem to have been known to the ancient Greeks and Romans. The ſouthern nations of Europe do not ſeem to have an appropriate name for it even at this day. The Italians have only the diminutive *Uvetta*. At Geneva they call it *Raiſin de Mars*. In France it has no appellation diſtinct from the Gooſeberry, but is named if I miſtake not *Groſeilles en grappes*. The ſhrub of both has the name of *Groſeiller*, with the epithets *commun* and *epineux*. The Germans call them both *Johanni-beere*, with the epithet *gemeine* for the Currant, and *glatte* for the Gooſeberry. The old French name *Groſeilles d'outre mer*, and the Dutch *Beſkins over zee*, proclaim their having been ſtrangers imported. The Northern nations have ſeparate appellations for theſe fruits: in different provinces of Sweden the Currant is called *Winbar*, *Reps* and *Riſp*; and the Gooſeberry *Kruſhar* and *Stackelbar*. Our Engliſh name of *Currant* is evidently from the ſimilitude of the fruit to that of the *Uva corinthiaca*, the ſmall Grape of Zante, or the common grocer's *Corinths* or *Currants*.

2. Height three or four feet. Bark blackiſh red, finally aſh-colour. Racemes ſcattered all over the trunk and branches, ſolitary, when in flower always upright, and even when in fruit ſometimes ſo, if there be only one or two berries. Flowers elegant, relatively large, ſcattered on ſhort pedicels, which have a ſtill ſhorter bractæ at their baſe. Germ green; but the calyx on the top of it roſe-coloured or ſometimes blood-red, ſhaped like a diſh, half five-cleft, with a wheel-ſhaped border, having five plaits of a deeper red. Petals ſmall, white, rounded at the edge and entire, ſeſſile on the plaits of the calyx. Berries large,

[a] Juſſ. gen. [b] Smith. [c] Withering. [d] Woodwille. [e] Withering. [f] Ray ſyn.

very

very deep red, extremely acid, and not loſing their acidity by culture, and full of juice, but leſs glutinous than in R. alpinum. The leaves grow moſtly at the ends of the branches, ſo as to conceal the bunches of flowers and fruits: they are much larger than thoſe of R. alpinum, and uſually three-lobed, the lobes more or leſs acute, and ſerrate; they are naked, at firſt bright green, but becoming afterwards very dark; the petiole is ciliated with longer hairs. This ſpecies and the common garden Currant have been inoculated on each other, but without changing their nature. The R. petræum has been cultivated many years without changing its acidity or acerbity; but it once produced white fruit [g].

It is diſtinguiſhed from R. ſpicatum, by the flowers being in racemes. The fruiting racemes are pendulous; and it is entirely different from R. alpinum [h]. Dr. Smith remarks, that it has altogether the appearance of R. ſpicatum, and doubts whether it be diſtinct, as a ſpecies, from that.

Native of Carinthia, Styria, Sileſia, Bohemia, England. The Rev. Mr. Harriman found it near Egleſton, and Mr. Robſon near Conſcliffe, in the county of Durham [i].

3. Stems concealed in the moſs, ſcarcely thicker than a ſwan's quill; branches filiform, procumbent alſo in the moſs, till within a ſpan of the end, where they riſe up and are herbaceous. Leaves on long petioles, three-lobed, much broader than they are long, entire at the baſe, which is almoſt ſtraight; the lobes are ſerrate, the ſide ones ſomewhat gaſhed; the lower ſurface and the petioles are ſlightly hairy. Racemes axillary, five, ſix, or ſeven-flowered, naked, in flowering-time upright. Flowers of the ſame ſhape and ſtructure with thoſe of R. rubrum, but ſmaller, ſpreading with five, livid-purple, pubeſcent, acute ſegments. Anthers ſcarcely prominent from the calyx. Berries often larger than thoſe of the Black Currant, hanging down from almoſt erect racemes, yelloviſh green, or when ripe rufeſcent, very pleaſant to the taſte, and therefore in much requeſt in Dauria, where the ſhrub grows wild.

In Demidoff's garden at Moſcow, this ſhrub raiſed from ſeed grew taller and more robuſt [k].

4. Stem a foot and half in length, aſh-coloured. Branches alternate, longer than the ſtem, when bruiſed ſmelling ſtronger than the black Currant. Leaves ſpreading, cordate, five-lobed, the upper lobes leſs divided, unequally ſerrate, rolled back at the edge, acute, five-nerved, veined, wrinkled, when young pubeſcent, but afterwards ſmooth, void of ſcent, from three to four inches in length and breadth; petiole round, ſcarcely ſhorter than the leaf. Racemes lateral, on the year's ſhoots before the leaves come out, ſolitary, erect, becoming pendulous when fruiting, hiſpid. Flowers ſpreading, purpliſh, on purpliſh-hiſpid pedicels, at the baſe of each a linear-lanceolate, concave, ſubhiſpid bracte, much ſhorter than the pedicel and permanent. Calyx bell-ſhaped, with purple pedicelled glands. Petals wedge-form or deltoid, truncate, ſhorter than the calyx. Anthers purple. Germ truncate, pedicelled-glandular. Styles two, approximating as if united, diſtinct at top, reflexed, the length of the ſtamens. Berry hiſpid. Seeds from ſix to eight. Fruit eatable, but not good.

It differs by its creeping branches and pedicelled glands on all the outer parts of the inflorescence; from all the thornleſs ſpecies in having hiſpid fruits. The buds, eſpecially when the leaves are fallen, are more divaricate, and red, not pubeſcent, as in R. nigrum [l].

Native of North America. Introduced in 1777, by John Fothergill, M.D. It flowers in april and may [m].

L'Heritier ſays Le Monnier firſt cultivated it in France.

5. Leaves ſmaller than in the common Currant, (R. rubrum) three-lobed, ſerrate, ſmoothiſh, ſhining, eſpecially underneath; the ſegments lanceolate, pointed. Racemes always erect, with the flowers on ſhort pedicels, yelloviſh green. Calyx tubular, bluntly five-ſided. Bractes lanceolate, longer than the flower. Stamens ſhorter than the petals. Piſtil as long as the calyx. Berries elliptic, red, mucilaginous and inſipid; or with a flat ſweetiſh taſte, agreeable only to children. The wood being hard and tough, makes good teeth for rakes [n].

Native of Europe and Aſia, in woods, thickets and hedges. In England only in the northern parts: as in Yorkſhire, (Dodſworth) eſpecially about Bradford; (Richardſon) about Darlington, Durham; (Robſon) Edgbaſton, and Ilam in Staffordſhire, (Withering and Sneyd.) Flowering in april and may.

It has been obſerved both here and abroad to be ſometimes dioecous. Jacquin and Leers have remarked this. Grimm ſays it is conſtantly ſo: but Pallas thinks it proceeds from a weakneſs in garden plants. The female flowers, as found in Staffordſhire, had five imperfect ſtamens, and formed a ſhorter and more thinly ſet bunch, than the male flowers, which had five perfect ſtamens, and two ſtyles, but no germ [o].

6. This has the leaves of R. rubrum, but with ſharper lobes and ſerratures, and more tomentoſe underneath. Spikes always erect, with the flowers on very ſhort pedicels, of a reddiſh-brown colour. Bractes ovate, ſmall, ſcarcely exceeding the pedicel, but by no means the flower, in length, reflex at the tip. Petals wedge-oblong. Berries like thoſe of the Black Currant in colour and taſte [p].

It is not a hybrid plant, for its ſeeds are fertile. It approaches R. petræum in ſome reſpects, but the fruit of that is pendant. The upright ſpikes are ſufficient to diſtinguiſh it from all its brethren. The ſhortneſs of the bractes will prevent it from being taken for R. alpinum [q].

It was firſt diſcovered and deſcribed by Mr. Robſon, who had the firſt ſhrub from the neighbourhood of Richmond in Yorkſhire; and afterwards found it by the Tees between Pierſbridge and Gainford in the county of Durham [r].

7. This ſhrub is a foot and half in height, with the bark inclining to a teſtaceous colour; branches alternate, thoſe of the year dotted with a very yellow reſin that exſudes from them. Leaves on long petioles, ſmooth, coriaceous, obſoletely five-cornered, three-lobed, or ſometimes five-lobed ſerrate, underneath very much veined and more glaucous: from this ſurface they exſude, in very frequent little yellow drops, a very fragrant balſamic reſin, having a ſtrong ſmell approaching a little to that of the Black Currant, which it reſembles much in its whole appearance. Racemes ſhort, compoſed of about ten flowers, cluſtered, ſtiffly upright. Flowers bell-ſhaped, white, deeply five-cleft, ſmelling very ſtrong: petals lanceolate, acute, ſpreading. Bractes deciduous, ſmaller than in R. procumbens. The racemes, when in fruit, are elongated, but continue upright, except in a few inſtances when they bend with the weight of the fruit. Fruit at moſt the ſize of the Black Currant, red, and very ſweet.

Native of Siberia, on mountains bordering on Mongolia, where there are no woods.

8. From a creeping root this riſes two or three feet high with ſeveral upright ſhoots: at the end of theſe are a few leaves of the ſame ſhape as in R. rubrum. The flowering and fruiting racemes are pendulous and ſmooth. Corollas flattiſh, red without and yelloviſh within; the petals rolled back. Berries ſmall, black, inſipid, full of a blackiſh red juice, very excellent for colouring wines.

Native of Siberia, in the ſame parts with the preceding, and on the ſummits of the Jablennoi ridge [s].

9. The common Black Currant is diſtinguiſhed by its more humble habit, its ſtrong-ſmelling leaves glandular underneath, its hairy racemes, tubular calyx, and black fruit, but eſpecially by its ſolitary, one-flowered peduncle at the baſe of the raceme, and diſtinct from it [t].

[g] Wulfen in Jacq. miſc. [h] Smith. [i] Harriman in Smith brit. [k] Pallas. [l] L'Heritier. [m] Hort. kew. [n] Smith and Withering. [o] Withering. [p] Smith from Robſon. [q] Withering from Robſon. [r] Withering. [s] Willdenow from Pallas. [t] Smith.

Digitized by Google

The buds are glandular: the bractes woolly and as long as the pedicels; the flowers villose; the petioles also subvillose and glandular [x].

The petals are blunt; the style simple, scarcely half-divided by a groove; the stigma bifid [x].

Flowers turban-shaped. Segments of the calyx often of a rich brown red colour. Stamens sometimes more than five, and then there are fewer petals, so that when there are ten stamens there are no petals: this change of the petals into stamens is just the reverse of the process by which single flowers are known to become double; but it is the only fact of the kind that has been hitherto observed [y].

Native of most parts of Europe, especially the more northern parts; also of Siberia, especially the subalpine regions, by river sides and in woods; where the bunches and berries are very large and sapid; and of woods in the northern parts of Russia [z]. In Britain it is found in wet hedges, on the banks of rivers, in alder-swamps, and sometimes in woods; flowering in may.

The berries of the Black Currant have a very peculiar flavour, which many persons dislike; they are however commonly eaten in puddings in some parts of England, and make a tart little inferior to the Cranberry. The juice is frequently boiled down to an extract, with the addition of a small proportion of sugar; in this state it is called Rob, and is much used in sore throats, but chiefly of the inflammatory kind, in the same intention as gargles. The fruit from their efficacy in this way have acquired the name of Squinancy berries. The jelly in common domestic use for this purpose, is rendered less efficacious by having too much sugar in its preparation [a]. The officinal preparations in the London Pharmacopœia are, Syrupus ribis nigri, and succus ribis nigri inspissatus, the jelly and rob [b]. Some put the berries into brandy, for the same purpose as others put black Cherries [c]. The Russians make a wine of the berries alone, or fermented with honey, with or without spirits; or they mix the expressed juice with spirit drawn from wheat. They make a drink also of the leaves in Siberia [d]. The leaves when young tinge common spirits so as to resemble brandy: an infusion of them is said to have the taste of green tea, and is to some people peculiarly agreeable. They have been likewise recommended for their medicinal virtue, as cleansing, pellent and diuretic [e]. An infusion of the young roots is useful in fevers of the eruptive kind, and in the dysenteric fevers of cattle. Goats eat the leaves [f]; and bears are fond of the berries [g].

10. In this, as well as in the preceding, the leaves are covered with yellow or fulvous shining glandular dots, visible only in the microscope [h]; in this they are on both sides, but in the common Black Currant only underneath. Bractes linear, longer than the pedicel, produced half way the flower; whereas in R. nigrum they are very small, and shorter than the pedicel. Buds cinereous, not red. Racemes numerous, conspicuous, villose, hanging down very much. Flowers sulphur-coloured, ventricose-cylindrical; segments longer, revolute. Berries black [i].

According to Pallas, it agrees exactly with R. nigrum in its form and manner of growth, but differs in having the racemes a long span in length, erect, not pendulous; and the leaves, bark and berries without any smell.

Dillenius says that the stems are from a foot and half to three feet in height, covered with a bay-coloured bark, rather more slender than in the preceding, and with smaller leaves, divided into narrower lobes, more like those of Merret's R. fructu parvo (n. 1. γ.); when rubbed they smell somewhat like Savin, less strong than those of the common Black Currant, and of a paler green. Flowers oblong, pale, divided into longer segments than in the other sorts, upright, not spread out as in them. Berries black, oblong; the pulp purplish, having a vinous smell, and a taste like Strawberries, hardish and not viscid. Seeds small, roundish, brownish, somewhat wrinkled.]

[x] Linn. suec. [x] Leers. [y] Withering. [z] Pallas.
[a] Withering and Woodville. [b] Woodville. [c] Withering.
[d] Pallas. [e] Woodville. [f] Withering. [g] Pallas.
[h] Willdenow. [i] L'Heritier.

The shoots are much smaller and more compact than in the common Black Currant; the bark is of a darker colour; the leaves are smaller, thinner, smoother, and have not a rank smell. The flowers are smaller, bell-shaped, and grow in thinner bunches; the fruit is smaller and not so round. The plants do not produce much fruit here, and therefore are kept only by way of curiosity.

Native of Pennsylvania, whence it was sent to Mr. Peter Collinson, [who gave it to Dr. James Sherard, and it was cultivated in his garden at Eltham before 1732. It flowers in april and may [k].

11. This is a sort of intermediate species between the Currants and Gooseberries; it has a pair of prickles only at the buds; in other parts it is unarmed [l].

It has the habit of R. alpinum, but it is abundantly distinct both in the leaves and prickles [m].

This shrub is an ell and half in height, upright, and rod-like. Branches stiffly upright, with a whitish-gray bark, and somewhat subdivided. Prickles diverging, straightish or a little curved in, on the older branches and trunk obliterated. Leaves in bundles, three-lobed-gashed. Racemes among the leaves solitary, upright, many-flowered, with a linear bracte to each flower. Flowers flattish, small, greenish-yellow, with oblong, bluntish, spreading segments. Berries the size of R. alpinum, reddish, more dusky red when ripe, of a sweetish acid flavour, having four, or sometimes five, biggish, flatted seeds.

Native of Siberia; flowering in may. The berries dried are used there as we do the Currants of Zante [n]. Introduced in 1781, by Mr. John Bush [o].

In Demidoff's garden at Moscow, this species raised from seed, produced widish leaves, more rounded, and gashed: and some of the shrubs, as Jacquin observed in the Vienna garden, produced barren flowers, of which there are none in the wild plants.

A variety has been discovered in the high rocks of Mongolia, with leaves three times as big, deeply gashed, having several smaller prickles scattered round the axillary; but it had neither flower nor fruit [p].

12. This is an intermediate species between *alpinum* and *Diacantha*, with the habit of *Grossularia*, and a fruit like the true *Ribes* or Currant. It is nearly upright. Prickles on the branches scattered, solitary, like stiff bristles, straight, remote from the buds, worn off on the old wood. Leaves on long petioles, having a gash or two on the lobes. Both flowering and fruiting racemes upright, having seven or eight flowers, on longish pedicels, with linear bractes the length of the pedicel. Petals small, patulous, of a livid-green colour. Berries globular, when ripe red and somewhat acid, scarcely so big as the common red Currant. Native of Siberia [q].

13. The leaves are not only wider, but of a darker colour; prickles to each leaf one or two, but sometimes there are none; they are short and much weaker than in the common Gooseberry, besides others that are harmless and much shorter scattered over the branches. Fruit when ripe commonly dark purple, but sometimes red or even yellow [r].

Native of Germany; common in hedges all over Switzerland; fond of cold situations. It flowers in april, and the fruit is ripe in june and july. Clusius says that he first saw it at Leyden in 1594.

14. This is a branching shrub. Prickles under the buds one, two, or three. Leaves three-lobed, gashed, subpubescent. Petioles hairy, commonly longer than the leaves. Peduncles one-flowered, nodding, having one, two or three opposite ovate ciliate bractes in the middle. Germ villose. Berries pendulous, hairy [s].

If the bractes will not distinguish this from R. Uva-crispa, the roughness or smoothness of the berries will hardly do it, for Mr. Robson has observed, that seeds from the same plant will produce both rough and smooth fruit [t]. I cannot regard them as different species; and in other cases there seems to be a disposition to multiply species in this genus. Ray does not dis-

R I B

tinguiſh the Gooſeberries, but comprehends them all under the general terms of Uva criſpa, Groſſularia, or Gooſeberry-buſh.

Native of ſeveral parts of Europe. According to Mr. Robſon, it is common in woods and hedges about Darlington.

15. Buds woolly. Calyx bent back. Peduncle woolly. Bracte ovate, embracing, generally with three diviſions. Flowers ſolitary, pendant. Stipules ciliate with knobbed hairs. A triple thorn beneath the buds [s]. Berry crowned with the permanent calyx, peduncled, pulpy, ſubdiaphanous, pale, amber-coloured, red or purple, ſmooth; the pulp watery and ſweet. Receptacles formed of the ſkin of the berry thickened, oblong, narrow; with filiform umbilical chords, the length of the ſeeds, and inſerted into their inner and blunter extremity. Seeds as far as thirty, ovate-oblong, with a pellucid jelly about them, rufeſcent.

This differs from the preceding only in the ſmoothneſs of the berries, in having the bractes united into a tube at the baſe, and the hairs of the petioles glandular; all fallacious and uncertain marks [t].

Native of Europe, eſpecially the northern parts. It is common in Cambridgeſhire, Norfolk and other counties of England, but only in hedges, on walls and old buildings and decaying trees, where the ſeeds have been depoſited by birds: or if it be found ſometimes in woods, it has got there by the ſame chance. I am of opinion with Dr. Smith, that the Gooſeberry-buſh is apparently not truly indigenous.

Villars ſays that Ribes Groſſularia, in Dauphiné is five or ſix feet high, with wide leaves, that are villoſe as well as the fruit; and that it is common every where in the champain, in hedges. But that R. uva criſpa, which he calls *Le petit Groſeiller epineux ou ſauvage*, is only a foot or two in height, ſtraight, and wholly covered with yellowiſh ſtiff prickles, and is found in the mountains. This is evidently the Gooſeberry-buſh in its wild ſtate; and the other as it appears in cultivation: as to the ſmoothneſs or hairineſs of the fruit, it is merely accidental. I believe that the Gooſeberry is a fruit not eſteemed in the ſouthern countries of Europe. Monſ. De La Lande was ſurpriſed at the excellence of our Engliſh Gooſeberries, and aſſured me that they had not an appropriate name at Paris; I ſuppoſe he meant, diſtinct from the Currant, both being called *Groſeille*. Allioni ſays they are eatable, but ſomewhat aſtringent and neglected—"ſolent a noſtratibus negligi." In Piedmont they are called *Griſelle*, which is the ſame with the French. Our name *Gooſeberry* is probably derived from its being uſed as a ſauce with young, commonly called green Geeſe, at leaſt I know not any better reaſon for the name. Parkinſon ſays, that the berries whilſt they are ſmall, green and hard, are much uſed to be boiled or ſcalded to make ſauce, both for fiſh or fleſh of divers ſorts.

Gerarde ſays, it is called Fea-berry buſh in Cheſhire my native country. It has the ſame name in Lancaſhire and Yorkſhire. In Norfolk, it is abbreviated into *Feabes*, or as they pronounce it, *Fapes*. I do not know the origin of this, any more than of *Carberry*, which is ſaid to be another name.

The varieties in Parkinſon's Paradiſus, are "beſides "the common kind, which is of three ſorts, ſmall, "great and long; three red Gooſeberries, a blue and "a green."

Johnſon upon Gerarde has "the long green, the "great yellowiſh, the blue, the great round red, the "long red, and the prickly Gooſeberry."

Ray has no Engliſh name but *the Pearl* Gooſeberry.

Rea mentions the Red of three ſorts, the Blue, the Yellow of ſeveral ſorts, the White Holland, and the Green.]

Miller only ſays, there are ſeveral varieties obtained from ſeeds, moſt of them named from the perſons who raiſed them, as Lamb's, Hunt's, Edwards's Gooſeberry, &c. but as there are frequently new ones obtained, it is needleſs to enumerate them.

[It ſeems to have been a fruit in very little eſteem; but it has received ſo much improvement that it is now become valuable, not only for tarts, pies and ſauces, both freſh and preſerved in bottles, but as an early deſert fruit, and preſerved in ſugar for winter uſe, to anſwer the ſame purpoſe.

The varieties now beſt known, are of the Red; the hairy, ſmooth, deep red, damſon or dark-red blueiſh, red raſpberry, early black-red, Champaigne, &c.

Green; hairy, ſmooth, Gaſcoigne, Raſpberry, &c.

Yellow; great Oval, great Amber, hairy Amber, early Amber, large Tawney or Great Mogul, &c.

White; common, white-veined, and large cryſtal.

Beſides theſe, there is the Rumbullion, large Ironmonger, ſmooth Ironmonger, hairy Globe, and innumerable others, ſome of very large ſize, annually raiſed from ſeed; weighing from ten to fifteen pennyweights, but there are ſmall ones better taſted. There are ſaid to be upwards of two hundred, at leaſt in name.

16. This has more frequent and milder prickles than the common Gooſeberry; the leaves are ſmooth and more deeply cut; the fruit ſmall and round, the ſize and ſhape of a Currant; colour at firſt purple, but when ripe dark purple with a blue bloom; it is ſmooth, on a ſhort ſlender peduncle; the pulp ſubacid, duſky purple, with one or two brown ſeeds, of a round form ſlightly angular.

The ſtems are aſh-coloured, with frequent ſlender browniſh prickles, like the Burnet Roſe, but leſs rigid; the young ſhoots are pale green and have green prickles. Leaves ſomewhat paler underneath, the petioles beſet with harmleſs prickles; thoſe at the ends of the branches larger than the others. Flowers one or two from an axil, white and yellowiſh white [r].

Native of Canada. Cultivated, according to Plukenet, by Mr. Reynardſon, in 1705. It flowers in april and may [s].

17. This has the appearance of the other ſpecies, but the leaves are little gaſhed. Prickle like a thorn under the axils. Peduncles generally three-flowered. Germ in the flower hairy, but not prickly. It has the corolla of R. groſſularia. Berries the ſize of a hazelnut, armed all over with ſtout prickles [t].

Native of Canada. Cultivated by Mr. Miller in 1759. It flowers in april [u].]

PROPAGATION AND CULTURE.

Theſe are propagated either by ſuckers taken from the old plants, by layers, or by cuttings; the latter of which I prefer to the former, becauſe thoſe plants which are produced from ſuckers are always more diſpoſed to ſhoot out a great number of ſuckers from their roots, than ſuch as are raiſed from cuttings, which generally form much better roots.

The beſt ſeaſon for planting theſe cuttings is in autumn, juſt before their leaves begin to fall; obſerving always to take the handſomeſt ſhoots, and from ſuch branches as generally produce the greateſt quantity of fruit; for if you take thoſe which are produced from the ſtem of the old plants (which are commonly very luxuriant) they will not be near ſo fruitful as thoſe taken from bearing branches: theſe cuttings ſhould be from ſix or eight to ten or twelve inches long, and muſt be planted in a border of light earth, expoſed to the morning ſun, about three inches deep, obſerving to water them gently when the weather proves dry, to facilitate their taking root; and in the ſummer, when they have put out branches, you ſhould rub off all the under ſhoots, leaving only the uppermoſt or ſtrongeſt, which ſhould be trained upright, to form a regular ſtem. In october following theſe plants may be removed; at which time you ſhould prepare an open ſpot of freſh earth, which ſhould be well dug, and cleanſed from all noxious weeds, roots, &c. and being levelled, you ſhould proceed to take up your plants, trimming their roots, and cutting off all ſide branches; then plant them at three feet diſtance row from row, and one foot aſunder in the rows, obſerving to place ſome ſhort ſticks to the plants, in order to train their ſtems upright and regular. In this place they may remain one or two years, being careful to keep them clear from weeds, as alſo to trim off all lateral ſhoots which are produced

[s] Linn. [t] Smith.

[r] Dillenius. [s] Hort. kew. [t] Linn. [u] Hort. kew.

below

Digitized by Google

below the head of the plant; ſo that the ſtem may be clear about a foot in height above the ſurface of the earth, which will be full enough; and as the branches are produced commonly very irregular in the head, you muſt cut out ſuch of them as croſs each other, or thin them where they are too cloſe, whereby the head of the plant will be open, and capable of admitting the air freely into the middle, which is of great uſe to all kinds of fruits.

After theſe plants have remained in this nurſery one or two years at moſt, they will be fit to tranſplant to the places where they are deſigned to remain; for it is not ſo well to let them grow in the nurſeries too large which will occaſion their roots to be woody, whereby the removing of them will not only hazard the growth of the plants, but ſuch of them as may take very well will remain ſtinted for two or three years, before they will be able to recover their check. The ſoil in which theſe plants thrive to the greateſt advantage, is a rich light earth; though they will do very well upon middling ſoils, which are not too ſtrong or moiſt; and in all ſituations; but where the fruit is cultivated, in order to procure it in the greateſt perfection, they ſhould never be planted in the ſhade of other trees, but muſt have a free open expoſure. The diſtance they ought to be planted is eight feet row from row, and ſix feet aſunder in the rows. The beſt ſeaſon for tranſplanting them is in october, when their leaves begin to decay; obſerving, as was before directed, to prune their roots, and trim off all lateral ſhoots, or ſuch as croſs each other, ſhortening all long branches, ſo as to make the head regular.

In the pruning theſe ſhrubs common gardeners are apt to make uſe of garden-ſhears, obſerving only to cut the head round, as is practiſed for Evergreens, &c. whereby the branches become ſo much crowded, that what fruit is produced, never grows to half the ſize as it would do were the branches thinned, and pruned according to art; which ſhould always be done with a pruning-knife, ſhortening the ſtrong ſhoots to about ten inches, and cutting out all thoſe which grow irregular, thinning the fruit-bearing branches where they are too thick, obſerving always to cut behind a leaf bud. With this management your fruit will be near twice as large as thoſe which are produced upon ſuch buſhes as are not thus pruned, and the ſhrubs will continue in vigour much longer; but you muſt obſerve to keep the ground clear from weeds, and dig it at leaſt once a year; and every other year you ſhould beſtow a little rotten dung upon it, which will greatly improve the fruit.

It is a common practice with the gardeners near London, who have great quantities of theſe buſhes in order to ſupply the markets, to prune them ſoon after michaelmas, and then to dig up the ground between the rows, and plant it with Coleworts for ſpring uſe, whereby their ground is employed all the winter, without prejudicing the buſhes; and in hard winters theſe Coleworts often eſcape, when thoſe which are planted in an open expoſure are all deſtroyed; and theſe are generally pulled up for uſe in february or march, ſo that the ground is clear before the ſhrubs come out in the ſpring; which is a piece of huſbandry well worth practiſing where ground is dear, or where perſons are confined for room.

Currants, whilſt they remain in the nurſery, muſt be pruned and trained for the purpoſes to which they are deſigned; that is, to clear ſtems about one foot high, if for ſtandards, but if they are to be ſet againſt walls or pales, they muſt be trained up flat: but the beſt method is to train them againſt low eſpaliers, in which manner they will take up much leſs room in a garden, and their fruit will be much fairer. For this purpoſe they ſhould not be planted leſs than eight or ten feet diſtant, that their branches may be trained horizontally, which is of great importance to their bearing.

If they are planted againſt a ſouth-eaſt wall or pale, their fruit will ripen at leaſt a fortnight or three weeks ſooner than thoſe in the open ground; and againſt a north wall or pale it will be later: thus the fruit may be continued in uſe during ſix months, eſpecially if thoſe to the north be covered with mats.

Currants produce their fruit upon the former year's wood, and alſo upon ſmall ſnags which come out of the old wood; in pruning therefore, theſe ſnags ſhould be preſerved, and the young ſhoots ſhortened in proportion to their ſtrength: obſerving not to lay the ſhoots too cloſe, and never to prune the ſnags to make them ſmooth.

Theſe ſhrubs will thrive in almoſt any ſoil and ſituation, and are often planted under the ſhade of trees; but the fruit is always beſt when they are planted in the open air, and upon a light loamy ſoil.

[RIBESIOIDES. *Lin. zeyl.* is Embelia Ribes, *Burm. ind.* 62. and is referred by Gærtner (1. 189.) to *Antideſma*.

RIBESIUM. See *Ribes*.

RICCIA. (*So named by Micheli, in honour of Pietro Franciſco Riccio, Senator of Florence, and Preſident of the Order of St. Stephen.*)

Lin. gen. Schreb. n. 1666. *Mich. gen. t.* 57. *Schmid. ic. t.* 44, 45. *Hedw. theor.* 116. *t.* 29.

Claſſ. 24. 4. Cryptogamia Hepaticæ.—Algæ *ed. prior:*

GENERIC CHARACTER.

* *Male Flowers?* ſeſſile on the ſurface of the frond.

CAL. and COR. none.

STAM. *Anther?* conical, truncate, ſeſſile, opening at the top?

* *Female Flowers* on the ſame, or according to Micheli on a diſtinct plant.

CAL. none, except a veſicular cavity, within the ſubſtance of the leaf.

COR. none.

PIST. *Germ* turbinate. *Style* filiform, erect, reaching the ſurface of the frond or exceeding it. *Stigma* ſimple.

PER. *Capſule* ſeſſile, globular, one-celled, at the apex of the leaf, crowned with the ſtyle.

SEEDS very many, (twenty to thirty) hemiſpherical.

OBS. *The little bodies which Micheli takes for the anthers, ſeem to Schreber not to be different from the other papillæ on the ſurface of the frond, except in ſize. He conjectures that the tube on the germ is the anther, and the little granules within it, the pollen. He recommends the examination to be made before the germ becomes ſpherical.*

Linneus has five ſpecies, all natives of Europe; Withering has alſo the ſame number, natives of Britain, one of which, namely *R. fruticuloſa*, is the ſame with *Jungermannia furcata* of Linneus. Swartz has added another ſpecies (R. reticulata) from Jamaica; figured by Dillenius as a *Lichenoides*, in *t.* 19. *f.* 21. Theſe plants were formerly known under the names *Lichen*, *Lichenaſtrum* and *Hepatica*.

RICE. See *Oryza*.

RICHARDIA. (*So named by Linneus, from Richardſon, placed by Linneus among the Nomina Commendata. Boehmer ſays, à quo multa ſperaverat Linnæus, fruſtra.*)

Lin. gen. n. 439. *Reich. n.* 472. *Schreb. n.* 591. *Houſt. reliqu. t.* 9. *Gærtn. t.* 25. *Juſſ.* 198.

Claſſ. 6. 1. Hexandria Monogynia.

Nat. order of *Stellatæ*. *Rubiaceæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, ſix-parted, erect, acuminate, ſhorter by half than the corolla.

COR. one-petalled, cylindric-funnel-ſhaped: *border* ſix-cleft, acute, erect.

STAM. *Filaments* ſix, very ſhort. *Anthers* roundiſh, ſmall, at the inciſures of the corolla.

PIST. *Germ* inferior. *Style* filiform, the length of the ſtamens, three-parted at top. *Stigmas* blunt.

PER. none.

SEEDS three, round on one ſide, angular on the other, at top wider, gibbous.

OBS. *It varies, according to Gærtner, with the calyx and corolla eight-cleft, and eight ſtamens.*

ESSENTIAL CHARACTER.

Cal. ſix-parted. *Cor.* one-petalled, ſubcylindric. *Seeds* three.

DESCRIP-

Digitized by Google

DESCRIPTION, &c.

Stem high, brachiate, ſomewhat jointed, obſoletely four-cornered, hiſpid with ſtiffiſh ſcattered reflex hairs. Leaves lanceolate-ovate, alternately nerved, quite entire, ſubpetioled, rugged. Flowers in terminating heads, and alſo heaped into whorls; the former radiate with four or more leaves, alternately larger and ſmaller. Corollets as in Aſperula, ſlender and long, but ſix-cleft; and the fruit conſiſting of three ſeeds: thus it differs from Spermacoce in number and other circumſtances [c].

The calyx is ſometimes eight-parted, and ſuch flowers have eight ſtamens; it is hiſpid and the length of the fruit: which Gærtner conſiders as a Capſule, becauſe the ſeeds have an outer cruſt of a different colour, and ſeparable from them. He deſcribes this Capſule as inferior, compound, tricoccous, inverſely conical, ſubtrigonal, three-celled, tripartile, the three component parts (cocculi) are coriaceous, valveleſs, oblong but thicker upwards, on one ſide convex and rugged, on the other ſmooth, angular, prominent into a longitudinal ridge. Seeds in each part one, obovate, ruſeſcent, on one ſide convex and ſmooth, on the other having two grooves with a raiſed ſtreak between them, faſtened at the baſe [d].—Found by Houſtoun at Vera Cruz.

RICHERIA. (*So named by Vahl, in memory of Pierre Richer de Belleval, Profeſſor of Botany at Montpelier.*)

Vahl ecl. 1. 30.

Claſſ. 22. 5. Dioecia Pentandria—or 23. 2. Polygamia Dioecia.

GENERIC CHARACTER.

* *Male Flower.*

CAL. *Perianth* one-leafed, permanent, inferior, four-cleft or five-cleft: *clefts* ovate, acute, ſubtomentoſe: (three-leaved, very ſmall, *Ryan.*)

COR. *Petals* four or five, roundiſh, the length of the calyx:—(one-petalled, with five concave ſegments, *Ryan.*)

Nectary four or five glands at the baſe of the germ.

STAM. four or five (ſometimes ſix, *Ryan.*) between the glands of the nectary, erect, longer than the calyx, (length of the corolla, *Ryan.*) *Anthers* oblong, erect, (twin, *Ryan.*)

PIST. *Germ* conical, villoſe. *Style* none. *Stigma* none.

* *Female Flower.*

CAL. and COR. as in the Male.

Nectary a rim round the baſe of the germ.

STAM. none.

PIST. *Germ* ſuperior, ovate. *Style* very ſhort. *Stigmas* three, revolute, channelled above. (*Stigma* bicapitate, *Ryan.*)

PER. *Capſule* corticate, ſubovate, ſmooth and even, three-celled, having ſix valves opening from the baſe.

SEED one in each cell, berried, pendulous below the tip of the columella.

OBS. *According to Ryan, the fruit is a capſular berry, or a berried capſule.*

ESSENTIAL CHARACTER.

Capſ. corticate, ſix-valved, three-celled. *Seeds* ſolitary, pendulous below the tip of the columella. *Style* trifid.

SPECIES.

1. Richeria grandis.

Vahl, ecl. 1. 30.

DESCRIPTION, &c.

This is a large Tree, having the habit of Mammea americana. Branches round, the thickneſs of a gooſe quill, rigid, angular at the end, warted, ſmooth. Leaves moſtly at the ends of the branches, alternate, frequently ſix or ſeven inches in length, on a ſhort petiole convex underneath and channelled above, elliptic or obovate, attenuated at the baſe, acute, commonly blunt at the end, but ſometimes ſharpiſh, quite entire, ſomewhat coriaceous, ſmooth on both ſides, almoſt veinleſs on the upper ſurface, but veined underneath and paler. Spikes axillary, ſolitary, three times ſhorter than the leaf, commonly ſimple, but ſometimes having a ſpreading branch at the baſe. Flowers frequent, ſcattered, ſeſſile; each has a concave ovate bracte, almoſt the length of the calyx. Peduncle angular, appearing villoſe when examined by a microſcope. Capſule the ſize of a hazel nut, having ſix obſcure longitudinal ſutures; the outer valves are ſuberous, the inner ſubcartilaginous and flexible: partitions membranaceous and thin: columella woody, three-cornered, gradually a little thicker upwards, curved at the tip, after the valves are opened unequally three-winged from the remains of the partitions adhering. Seeds inverted, oblong, three times ſhorter than the cell, flattiſh on the inner ſide, obovate, convex: integuments four; the firſt a ſubcartilaginous diaphanous pellicle, the ſecond pulpy, the third a cruſtaceous ſhell, the fourth a thin membrane: albumen the ſame figure with the ſhell and whitiſh; embryo the ſize of the albumen, radicle ſuperior roundiſh, cotyledons cordate-roundiſh, leafy, of a pale yellowiſh colour. Beſides the male and female flowers, Ryan ſaw ſome that were hermaphrodite. He diſcovered this very rare tree in Montſerrat, in one place only, where fifteen or twenty trees all together filled up a ſmall valley among the high mountains [e].

Dioecous, leaves cordate acuminata.

DESCRIPTIONS, &c.

1. This is ſtouter than the common ſort at the ſame age. Stem the firſt year red and ſhining very much; afterwards aſh-coloured with duſky-purple ſpots. Leaves green on both ſides, the larger ones almoſt a foot and half in diameter, on a petiole a foot in length. Glands the ſame in number and ſituation as on the common ſort, but either wholly green, or elſe reddiſh with a green top. Calyx reddiſh green. Germ ſomewhat wrinkled, dark purple. Fruit ovate, larger, ſhining, dark green, ſomewhat wrinkled, but without the leaſt appearance of prickles [f].

It can ſcarcely be regarded as a diſtinct ſpecies. Miller has two ſpecies without prickles: *rugoſus*, n. 4. which is undoubtedly the ſame with this of Jacquin's, and *inermis*, n. 6. The former native of both Indies; the latter of the Spaniſh Weſt Indies.]

2. The common Palma Chriſti of Europe riſes with a ſtrong herbaceous ſtalk to the height of ten or twelve feet; the joints are at a great diſtance from each other; the ſtalk and branches are of a gray colour; the leaves are large, and on long foot-ſtalks; they are deeply divided into ſeven lobes, and are gray on their under ſide. The flowers are diſpoſed in long ſpikes, which ſpring from the diviſion of the branches: the males are placed on the lower part of the ſpike; the females, which occupy the upper part, have prickly calyxes.

[The root is biennial, long, thick, whitiſh, and beſet with many ſmall fibres. Stem round, thick, jointed, channelled, glaucous, of a purpliſh red colour towards the top [g]. The capſule is ſubglobular, corticate, echinated all over with ſmall ſpines, tricoccous: rind herbaceous, thin: the three component parts or cells (cocculi) ovate, papery, on one ſide convex with a dorſal ſtreak, on the other angular and perforated with a cordate hole below the tip, two-valved but ſeldom or ever opening, at leaſt in Europe. Receptacle columnar, three-cornered, widening above, entering by a triple blunt end the ventral perforations of the cells. Seeds ſolitary, biggiſh, ovate, convex on one ſide, very bluntly angular on the other, ſmooth, ſomewhat ſhining, ſometimes livid with cloudy ſpots, ſometimes variegated like the abdomen of the ſpider with white lines, dots and ſtains on a teſtaceous or brown ground; on the top is a fungous thick white umbilicus or navel [h].

Loureiro deſcribes the ſtem as eight feet high, upright, round, of an even ſurface, with a few ſpreading branches. Leaves eight-parted; the ſegments lanceolate, ſerrate, ſpread out in a ring: petioles very long, ſtraight, ſmooth, hollow, ſcattered. Flowers in terminating racemes: the males below, with a five-parted calyx, and about one hundred oblong white anthers in different bundles; females at the top, having the calyx commonly five-parted, and three red filiform bifid ſtigmas. Capſule roundiſh, villoſe-echinate. Seeds ovate, ſhining, black dotted with white. There are two varieties of it with the ſtem and petioles whitiſh, and with the ſame parts red.

This plant, which in our gardens is annual and herbaceous, in Africa becomes a tree [i]. In Candia it continues many years, and according to Belon, requires a ladder to come at the ſeeds. Cluſius relates, that he obſerved it in Spain, of the ſize of the human body, and the height of three men. And Ray ſaw it in Sicily, frequent in the hedges, as big as our common Elder trees, woody, and long-lived [k].

The ſeveral varieties are natives of the Eaſt and Weſt Indies, China, Cochinchina and Japan, about Tripoli in Syria; Africa, and the South of Europe.

It was cultivated in England in 1562, as appears from Turner's herbal. It flowers here in july and auguſt [l].

An oil extracted from the ſeeds of this plant, and known by the names of oleum Ricini, Palma Chriſti or Caſtor oil, has lately come into frequent uſe, as a quick but gentle purgative. The London College direct this oil to be expreſſed from the ſeeds in the ſame way as that of Almonds, and without the aſſiſtance of heat, by which method it would ſeem to be obtained in the pureſt ſtate: but we have ſome reaſon to believe that this method is ſeldom practiſed, and that the oil uſually employed here is imported from the Weſt Indies, where it is commonly prepared by freeing the ſeeds from the huſks, bruiſing them in a mortar, tying them up in a linen bag, throwing them into a large pot, with about eight gallons of water to one gallon of ſeeds, and boiling them till the oil is riſen to the ſurface, when it is carefully ſkimmed off, ſtrained and kept for uſe. Thus prepared, the oil is entirely free from acrimony, and will ſtay upon the ſtomach even when it loaths moſt other medicines; but its mildneſs ſeems to be chiefly owing to the action of the fire; for the expreſſed oil, as well as the mixt juices of the ſeeds, is far more active and violent in its operations [m]. Mr. Long affirms, that the oil intended for medicinal uſe is more frequently cold-drawn, or extracted from the bruiſed ſeeds by means of a hand-preſs; but remarks, that it is thought more acrimonious than what is prepared by boiling. It is well known however, that the oil obtained by boiling becomes much ſooner rancid than that by expreſſion. The beſt oil is limpid, and deſtitute of taſte or ſmell.

Dr. Cullen obſerves, that Caſtor Oil, when the ſtomach can be reconciled to it, is one of the moſt agreeable purgatives we can employ. It has theſe advantages, that it commonly operates in two or three hours, ſeldom gripes, and is generally moderate in its operation: it is particularly ſuited to caſes of coſtiveneſs,

[f] Jacquin. [g] Woodville. [h] Gærtner. [i] Deſfontaines. [k] Ray hiſt. [l] Hort. kew. [m] Browne.

Digitized by Google

and even of ſpaſmodic colic; is one of the moſt certain remedies in the dry belly-ach or colica pictonum; has been experienced to be uſeful in various febrile complaints, in bilious colics, nephritic caſes, worms and eſpecially the tape-worm. It is not heating or irritating to the rectum, and is therefore ſuited to hæmorrhoidal perſons. The only inconvenience attending this medicine is, that it is nauſeous to thoſe who diſlike oil, and that when the doſe is large, it occaſions ſickneſs at the ſtomach. The moſt effectual means to obviate this, is to take it in a little ardent ſpirit. In the Weſt Indies they uſe rum for this purpoſe, but compound tincture of ſenna is much better. This, in the proportion of one part to three parts of the oil, intimately mixed by being ſhaken together in a phial, makes the oil leſs nauſeous and therefore ſit better on the ſtomach. The common doſe of Caſtor Oil is a table ſpoonful or half an ounce, but many perſons require a double quantity. It is remarkable, that if this medicine be frequently repeated, the doſe may be gradually diminiſhed; inſomuch that perſons of a coſtive habit, who at firſt required half an ounce or more for a doſe, have afterwards found two drams enough, at leaſt to keep the belly regular[n].

The Ricinus is called Oil-nut tree in our Weſt Indian iſlands, and the oil is burned in the boiling-houſe lamps, by many of the ſugar-planters. The roots are looked upon as ſtrong diuretics, and the leaves are generally uſed to dreſs bliſters, of which they make too frequent uſe in that part of the world[o].

In China, the oil is rendered eſculent and palatable, but is ſeldom uſed in medicine[p].

In Japan, the ſeeds pounded with Moxa and Touche (Japan ink) together, are put into a little box or caſe, over which a piece of ſilk is ſtretched, and that is beſmeared with oil, that the powder underneath may be moiſtened by it. Whenever a Japaneſe has occaſion to put his ſeal, which is often curiouſly wrought in horn, to any thing, he firſt dips the ſeal into this box, and then impreſſes it upon the writing. Thus this powder ſupplies the place of printer's ink, and it is therefore neceſſary, that the ſilk ſhould be moiſtened afreſh with oil, as faſt as it dries[q].]

Varieties.

β. This has brown ſtalks, which divide into two or three branches, and riſe ſix or ſeven feet high; the leaves are broader, and not ſo deeply divided; they are of a deep green on both ſides, and are unequally ſerrate. The ſpikes of flowers are ſhorter, the ſeed-veſſels rounder and of a browniſh colour, and the ſeeds are much leſs and brown.—Native of the Weſt Indies.

γ. Stem thick, herbaceous, and of a grayiſh green, with the joints not ſo far aſunder as in the two preceding. It riſes about four feet high, and divided at the top into three or four branches, which ſpread out almoſt horizontally. The leaves are large, of a deep green on their upper ſide, but grayiſh on their under; they are deeply cut into ſix or ſeven (ſometimes eight) lanceolate ſegments, which are unequally ſerrate. The petioles ſpread out more horizontally than thoſe of the common ſort, and are much ſhorter. The principal ſtalk and branches are terminated by looſe ſpikes of flowers. The covers of the capſules are green, and cloſely armed with ſoft ſpines. The ſeeds are ſmaller and lighter coloured than thoſe of the preceding.—This alſo is a native of the Weſt Indies.

δ. This riſes with an herbaceous ſtalk about four feet high, the lower part is purpliſh, and the upper deep green, the joints are pretty far aſunder. The leaves are of a deep green on their upper ſide, but paler underneath; they are not ſo deeply divided as ſome of the others, and are more regularly ſerrate. The ſpikes of flowers are large: the males have more ſtamens, with yellow anthers. The capſules are oval and wrinkled, but have no prickles. The ſeeds are ſmall and brown. It is a native of both Indies. [This having no prickles on the capſules, probably belongs to the firſt ſpecies, if that be really diſtinct, as well as n. 6. of Miller, which he ſays] is in every reſpect like the African variety (ε or n. 5.) except that the capſules are ſmooth. It is a native of the Spaniſh Weſt Indies, whence Mr. Robert Millar ſent the ſeeds.

ε. This riſes with a large reddiſh ſtalk to the height of ten or twelve feet, with many joints, and dividing into ſeveral branches. Leaves very large, ſome meaſuring more than two feet and a half in diameter; they are of a dark green, unequally ſerrate, and not ſo deeply cut as in ſome of the varieties. The ſpikes of flowers are large, the calyxes brown, the anthers whitiſh. Capſules large, oval, and cloſely ſet with ſoft prickles. The ſeeds are very large and beautifully ſtriped.—Native of Africa and both Indies.

ζ. Of this there are two varieties, one with a red, the other with a pale green ſtalk, diſtinguiſhed in America by the names of red and white Oil-ſeed. The ſtems ſeldom riſe more than three feet high, ſometimes dividing at the top into two or three branches. The leaves are much ſmaller and more deeply divided than in the other varieties, their borders are unequally ſerrate, and the ſegments of the leaves are frequently cut on the ſides. The ſpikes of flowers are ſmaller and more compact. The capſules are alſo ſmaller, rounder, of a light green, and cloſely ſet with ſoft prickles. Seeds ſmall, and finely ſtriped.—Native of Carolina and other parts of America.

[η. This becomes an evergreen tree, ten feet in height, and more. The trunk, during the firſt year is blood red and very ſhining; afterwards it becomes woody, as thick as the wriſt, hollow with tranſverſe ſepta, pithy, with circular warts at the joints from fallen ſtipules, aſh-coloured, interruptedly and ſlightly ſtreaked. Before the leaves come out, they are wrapped up in red ſtipules like ſheaths, that fall off ſoon after. The leaves are divided half way into eight, ſometimes ten lobes, which are ſerrate and acute, and the petiole is long; they are of a dark blood-red colour on the upper ſurface, and livid on the lower, with blood-red veins, the largeſt leſs than a foot in diameter, quite ſmooth without any hairineſs whatever. Petioles round, blood-red, with two remote glands, of the ſame colour, and obliquely truncate, above the baſe; and two others on the upper part in front, placed near each other, roundiſh, concave, ſometimes united into one. Other glands ſimilar to thoſe now and then appear on the ſtem and branches, ſitting on each ſide of the axils of the leaves. Such glands are not found on the common Ricinus. The calyx is blood-red; the diviſions are lanceolate, acute, ſpreading very much, and concave. Filaments in about ten bodies, with globular, twin, yellow anthers. Piſtil blood-red. Fruit of a livid colour, with long ſoft prickles. Seeds ſhining, variegated with black and brown.—Native of the Eaſt Indies[r].

3. This is a middle-ſized tree, with twiſting ſpreading branches. Leaves ſuboval, ſubacuminate, ſmooth, whitiſh on the upper ſurface, odorous, ſcattered, on long petioles. Racemes ſimple, long, ſubterminating. Flowers hermaphrodite, apetalous. Calyx three-leaved: leaflets ovate-lanceolate, curved, ſpreading, deciduous. Filaments diſtinct, about thirty, adhering to the receptacle, longer, than the calyx. Anthers two-lobed, roundiſh. Germ three-cornered, ſuperior. Style thick, ſhort. Stigmas three, filiform, reflex. Capſule three-lobed, ſmooth, three-valved, three-celled; with ſolitary, roundiſh ſeeds[s].

Native of the Eaſt Indies, and the woods of Cochinchina.

4. Native of Ternate, the Molucca iſlands, and Tanna in the South Seas.

5. This is a ſhrub, four feet high, and very much branched. Leaves not peltate, rounded at the baſe, ſmooth, whitiſh underneath, ſcattered, on long petioles. Stigmas three, ſeſſile, undivided, woolly, reflex. Capſule extremely villoſe.—Native of China, about Canton[t].

6. Native of the iſland of Tanna[u].]

PROPAGATION AND CULTURE.

These plants are generally annuals in these countries, though in their native places of growth they continue longer; and in England the plants are often preserved through the winter, but young plants are much preferable to those which are thus preserved; therefore few persons are at the trouble to keep them, unless when the seasons prove so bad as that their seeds do not ripen, whereby the species might be lost, if the plants are not preserved through the winter.

These plants are propagated by seeds, which must be sown upon a hot-bed in the spring, and when the plants are come up, they should be each planted into a separate pot filled with light fresh earth, and plunged into a fresh hot-bed, observing to water and shade them until they have taken root; after which they must have a great share of free air when the season is mild, otherwise they will draw up tall, and be very weak; and as these plants grow very fast, their roots will in a short time fill the pots; therefore they should be shifted into larger pots, filled with the like fresh earth; and towards the end of may, when the season is warm, they may be hardened to endure the open air by degrees; and then if some of the plants are shaken out of the pots, and planted out into a very rich border, and in dry weather duly watered, they will grow to a very large size, and produce a great quantity of flowers and seeds: but if you intend to preserve any of the plants through the winter, they must not be planted in the full ground, because after their roots have been widely extended, there will be no transplanting them with safety; therefore the best way is to shift them into larger pots from time to time, as their roots shall require, placing them in the open air during the summer season in some warm situation, where they may remain until october, when they must be removed into the house with other exotic plants, observing to water them sparingly in winter, and also to admit the free air in mild weather; for they only require to be protected from frost and cold winds, so that they will endure the winter in a warm green-house, without any addition of artificial warmth.

These plants deserve a place in every curious garden for the singular beauty of their leaves (notwithstanding their flowers make no great appearance) especially those which may be propagated every year from seeds; because those persons who have no green-house to place them into in winter, may cultivate them as other annual plants, amongst which these being placed either in pots or on borders, afford an agreeable variety; but it must be observed, as these are large-growing plants, never to place them too near others of less growth, because they will overbear and destroy them; and those which are planted in pots, should be allowed room for their roots to spread, and must be frequently watered, otherwise they will not grow very large.

5. Rittera pinnata.
Vahl, ecl. 2. 38.
Leaves pinnate.

DESCRIPTIONS, &c.

1. Branches round, smooth, brown, with raised scattered white dots, angular at the end. Leaves alternate, ovate, three inches long, very smooth, veined, quite entire, blunt, emarginate. Petiole very short, slightly margined, two-toothed at the top, convex underneath. Stipule on both sides setaceous, rigid, erect, deciduous. Peduncles axillary and terminating, solitary or sometimes in pairs, much shorter than the leaf. Flowers in racemes, four or five on each peduncle, before they open, globular and the size of a pea. Calyx smooth, coriaceous, thick, bursting into four oblong equal segments. Petal large, clawed, veined, twice as long as the calyx. Stamens numerous, the length of the corolla. Germ lanceolate, sharp at both ends, double the length of its pedicel.—Native of the Caribbee islands *.

2. This is a middle-sized tree, with round smooth subdichotomous branches, of a brown colour, except the younger ones, which are green. Leaves alternate, three inches long, very smooth on both sides, veined,

* Vahl, symb.

somewhat

Digitized by Google

ſomewhat waved, a little acuminate, blunt, the midrib underneath yellowiſh. Petioles ſhort, with an obſolete toothlet on each ſide at the tip. Stipule on both ſides ſetaceous, ſtiffiſh. Peduncles from the upper axils and the end of the branches, ſolitary, ſhorter than the leaf, ſmooth, generally three-flowered. Pedicels alternate, an inch long, a little thicker towards the flower. Bracte minute, on each ſide at the baſe of the pedicels. Calyx coriaceous, burſting into two, three or four unequal obovate parts, three times ſhorter than the petal; which is clawed, roundiſh-reniform, an inch and half long, nerved and veined, both nerves and veins diſappearing towards the periphery. Filaments ſhorter than the petal; about fifteen of them longer and ſtouter than the reſt declining with the piſtil to the ſide oppoſite to the petal; the reſt are ſhorter, more ſlender, and incumbent on the petal. Germ linear, leſſening to both ends, ſmooth and even, ſhorter than the petal: ſtigma ſharp. Legume pedicelled, two inches long, ſharp at both ends, terminated by the ſtyle, containing one or two ſeeds, and contracted between each. Seed oval, an inch long, nearly as thick as the middle finger, black and ſhining: navel ventral, linear: aril incomplete, covering the ſeed almoſt to the oppoſite margin, orbicular, ſomewhat fleſhy, many-parted; ſegments linear, a little wider outwards, parallel, cohering only at the baſe.

This reſembles the preceding ſo much, that it is difficult to aſſign any infallible limits between them: but the leaves are narrower than in this, more acuminate, and of a thinner texture; the apex of the petiole has an obſcure tooth, but by no means running down the petiole, the peduncles are commonly no more than three-flowered, and the petals are larger. When the petals and legume ſhall be examined more accurately, we ſhall perhaps know better whether theſe be diſtinct ſpecies or not.

Native of the iſland of Trinidad [y].

3. Branches round, pubeſcent at top. Leaves alternate, two inches long, ovate, rounded at the baſe, acuminate with a blunt point, emarginate, membranaceous, very ſmooth, veined, quite entire. Petiole very ſhort, with a very ſmall tooth on each ſide a little below the baſe of the leaf. Stipule on each ſide, ſetaceous, upright, the length of the petiole. Racemes axillary, ſhorter than the leaf. Peduncles filiform: pedicels remote, an inch long, a little thickened. Bractes two at the baſe of the pedicels, ſetaceous. Calyx four-parted: ſegments oblong, ſmooth, very ſhort. Petal ſmall, oblong, the length of the calyx. Filaments from fourteen to nineteen, yellow, twice as long as the calyx: anthers globular. Germ the length of the filaments, attenuated to each end.

This is more tender and ſmaller in all its parts than the firſt ſpecies, the leaves are rounded at the baſe, inſtead of the teeth of the petioles there are two minute tubercles; but in the number of ſtamens, the figure and ſize of the petal this is very nearly allied to that.—Native of South America [z].

4. This is a middle-ſized tree, with a trunk from ſeven to eight feet in height, and ſeven or eight inches in diameter, with a ſmooth, thin, gray bark, and a yellowiſh, hard, compact wood. It divides at top into twiſted branches that extend themſelves on all ſides. Leaves alternate, compoſed of three ſeſſile leaflets, which are entire, ſmooth, thin but firm, ovate, acuminate; the middle leaflet much larger than thoſe on the ſides. Stipules two, ſmall, deciduous, at the baſe of the midrib. Flowers axillary, in corymbs, with two bractes at the baſe of the peduncle and each pedicel. Leaflets of the calyx two, three or four. Corolla yellow. Stamens twenty-five or twenty-ſix, ſix or ſeven of which are ſhorter and abortive. Seeds from one to four, of a diſagreeable taſte, and very acrid, inflaming and ſwelling the lips of thoſe who bite them.

Native of the foreſts of Guiana, near the ſource of the creek of the Galibis; flowering and fruiting in the month of may. The French call it *Bois dard* or *Bois a fleche*, becauſe the natives arm their arrows at the point with a piece of the wood cut very ſharp [a].

5. Branches round, ſmooth. Leaves alternate, a foot long, unequally pinnate, with two pairs of leaflets: theſe are oppoſite, about a ſpan in length, the inner ones ſmaller, elliptic, ſmooth on both ſides, very finely veined, quite entire, acuminate: general petiole roundiſh, flatted above at the leaflets; partial very ſhort, toothleſs. Racemes ſometimes two together, half a foot long: common peduncle round at bottom and dotted, angular above, gray with a very fine nap, as are alſo the pedicels and calyxes: pedicels ſcattered, frequent, an inch long, flatted a little, from upright ſpreading, one-flowered. Calyx before it opens globular, the ſize of a pea, membranaceous, burſting. Petal twice as long as the calyx. Two of the filaments oppoſite to the petal, aſcending, longer and ſtouter than the reſt; the reſt ſhorter, more ſlender, and incumbent on the petal. Germ flexuoſe, oppoſite to the petal, linear, hoary, longer than the petal. Legume pedicelled, pendulous, often a ſpan long, the thickneſs of the thumb, roundiſh, contracted between the ſeeds, terminated by the ſtyle, which is an inch and half in length. Seeds from two to five, oblong-ovate, on a fleſhy filiform pedicel, twice curved at the baſe, adhering at top to the valves; they are pale yellow, with one end towards the baſe of the legume ſharp, the other flat: ſcar at the upper end, linear, orange-coloured: aril incomplete, veiled, covering the upper end of the ſeed, fleſhy, ſtriated, crenulate, whitiſh yellow, ending in the pedicel.—Native of the iſland of Trinidad.

The fructification of Swartzia agrees ſo exactly with that of R. pinnata, that it can ſcarcely be deemed to form a diſtinct genus [b].]

RIVĪNA. (*So named by Plumier, in honour of Auguſtus Quirinus Rivinus, Profeſſor of Phyſiology and Medicine at Leipſic. Author of* Introductio in rem herbariam *and* Ordines Plantarum, 1690, 1691, 1699, fol. *ob.* 1723.)

DESCRIPTIONS, *&c.*

1. This grows taller than the ſecond, and the branches are more erect. The leaves are ſmaller, heart-ſhaped, and covered with ſhort hairy down. The ſpikes of flowers are not ſo long; the flowers are not ſo cloſely placed together, and have longer peduncles.

[Mr. Miller ſeparates this plant from the Rivinas or Rivinias, becauſe, as he affirms, the flowers have eight ſtamens. He gave it therefore the name of Piercea, in honour of Hugh Percy, duke of Northumberland.

Native of the Weſt Indies. Cultivated before 1699, in the Apothecaries garden at Chelſea, according to Moriſon[c]: who deſcribes the ſtems as a cubit high; leaves round at the baſe from an inch to two inches in breadth, running out into a point, reſembling very much thoſe of Circæa or Enchanter's Nightſhade, ſoft, pale green, pubeſcent with a very ſhort nap, on petioles an inch in length. Spike long, ſlender. Flowers ſmall, on ſlender pedicels, pale, divided into *five* parts and acute.

2. This reſembles the preceding very much, but is wholly ſmooth. The leaves are purpliſh about the edge. The flowers are red on the outſide[d].]

It riſes with ſhrubby ſtalks ſix or eight feet high, dividing into ſeveral ſpreading branches, and covered with a gray ſpotted bark. Leaves alternate, lanceolate, entire, two inches and a half long and one inch broad in the middle, drawing to a point at each end, ſmooth, of a lucid green, and pretty thick conſiſtence, on long ſlender footſtalks, and placed at pretty great diſtances on the branches. Flowers in long bunches, from the ſide and at the end of the branches, each on a ſlender peduncle near half an inch long: calyx ſcarlet: ſtamens *eight*, longer than the calyx. Berry roundiſh, with a thin pulp, outwardly ſcarlet changing to purple; incloſing one roundiſh hard ſeed.

[Gærtner, who ſeems to conſider this and the preceding as making one ſpecies, deſcribes the berry as ſmall, ſpherical, red terminated by a black callous dot; within one-celled, filled with a watery pulp tinging yellow. Seed lenticular, rugged with little ſoft briſtles, but under the outer cuticle very ſmooth, ſhining black.

Native of the Weſt Indies. Cultivated by Mr. Miller in 1733. It flowers moſt part of the year[e].]

Mr. Miller ſays of his *Piercea glabra*, that it riſes with a ſlender herbaceous ſtalk, three or four feet high, and by age becomes a little woody at bottom; that it divides into many herbaceous branches, which are angular; that the leaves are oval-lanceolate, near four inches long, and two broad in the middle, of a bright green, on ſlender foot-ſtalks an inch and half long; that the peduncles come out from the ſide of the branches, at the baſe of the petioles, are from four to five inches long, and ſuſtain a great number of ſmall white flowers, ranged along the upper part on both ſides; that the berries are ſmall, red, full of red juice, and incloſe one hard ſeed of the ſame form. Theſe berries hang on the branches in long bunches, great part of the year.

[3. This is diſtinct from the preceding in ſize, leaves, bigneſs and colour of the fruit, and time of flowering. Native of Braſil[f].]

4. This riſes with a climbing woody ſtalk to the height of twenty feet, covered with a dark gray bark. Leaves oval-lanceolate, near three inches long, and an inch and half broad, ſmooth, entire, on ſhort footſtalks. The flowers come out in long bunches from the ſide of the branches, ſhaped like thoſe of the ſecond ſort. The berries are blue, of the ſame ſize with thoſe of the other.

[Stamens four within the leaves of the calyx, alternate with eight others. Anthers haſtate. Style none. Stigma pencilled. Seed lens-ſhaped, ſhining[g].

The ſtem is commonly weak and ſuſtains its long flexile branches on other ſhrubs and trees; but ſometimes it is upright, and puts on the appearance of a very branching and not inelegant tree, fifteen feet high. Leaves oblong-lanceolate, acuminate, entire, very ſmooth, petioled, alternate, numerous, from three to to ſix inches long. Racemes few, ſimple, terminating the younger branches; and ſometimes others from the axils of the leaves. Calyx, in the flower white, in the fruit violet-red. Berries dark-purple, the ſize of a pea. Seed black. Stamens always twelve.—Loefling numbers from eight to twelve ſtamens, and deſcribes the berry as wrinkled, and the ſeeds as angular, whereas in Jacquin's plant, the ſeed has no angles, and the berry no wrinkles[h].

Browne ſays, it ſtretches a great way among the neighbouring ſhrubs and buſhes, the main ſtalk being ſeldom under an inch or two in diameter, and throwing out a few ſlender branches towards the top, which are generally adorned with flowers at their extremities. The berries make the principal part of the food of the American thruſh or nightingale; they contain a very oily ſeed, and after the bird has ſwallowed many of them, he frequently flies to the next bird-pepper buſh, (Capſicum) and picks a few of thoſe warm berries; nature doubtleſs having taught it what was neceſſary to promote the digeſtion of that oleaginous heavy food.

The ſtalk is very tough and flexile, and often made into hoops in Jamaica, when there is a ſcarcity of thoſe imported from Europe or North America, but they are not ſo ſtrong and durable. Hence the name of Hoop-Withe, given to this plant in Jamaica[i].

From the ſame circumſtance, the French in Martinico name this ſhrub *Lianne à baril*[k].

Native of the Weſt Indies. Cultivated before 1752 by Mr. Miller[l]:] who ſays that he received the ſeeds from Antigua, and that Dr. Houſtoun found it at the Havannah.

PROPAGATION AND CULTURE.

Theſe ſhrubs are propagated by ſeeds, which remain long in the ground before they vegetate; I have had them lie two years before the plants have appeared, but they never riſe the ſame year the ſeeds are ſown.

Theſe berries muſt be procured from the countries where they naturally grow, and when they arrive, ſhould be ſown in pots filled with freſh earth, and plunged into a moderate hot-bed. If this happens late in the autumn or winter, the pots muſt be plunged into the tan-bed of the ſtove; but if in the ſpring, they may be plunged in a common hot-bed under a frame. The earth muſt be moiſtened frequently in ſummer, to promote the vegetation of the ſeeds, but as they will not come up the ſame year, the pots ſhould be removed into the ſtove before winter, and plunged into the tan-bed; during the winter ſeaſon, the earth muſt be ſometimes refreſhed, but muſt not be too moiſt. In the ſpring the pots may be taken out of the ſtove, and plunged into a freſh hot-bed to bring up the plants; but if they ſhould not then riſe, the earth muſt not be diſturbed, becauſe the plants may come up the following ſeaſon.

When the plants come up and are two inches high, they ſhould be each tranſplanted into a ſeparate ſmall pot, filled with light loamy earth, and plunged into a

[c] Hort. kew. [d] Linn. mant. [e] Hort. kew. [f] Willdenow. [g] Linn. ſyſt. [h] Jacquin. [i] Browne. [k] Jacquin. [l] Hort. kew.

hot-bed, obſerving to ſhade them from the ſun till they have taken new root; after which they muſt be treated in the ſame way as other plants from the ſame countries.

Theſe plants being tender, cannot be preſerved in this country, unleſs they are kept in a warm ſtove, eſpecially while they are young; but when they have obtained ſtrength, they will live in a moderate warmth in winter, and in ſummer they may be removed into the open air, placing them in a ſheltered ſituation, where they may remain near three months in the warmeſt part of the ſummer. During the winter ſeaſon they ſhould be ſparingly watered, for as they grow naturally on a dry ſoil, much wet will deſtroy them, eſpecially in cold weather.

SPECIES.

1. Robergia fruteſcens.
Willd. ſpec. 752.
Rourea fruteſcens. *Aubl. guian.* 467. *t.* 187.

DESCRIPTION, *&c.*

This is a ſhrub five feet in height. Leaves alternate, unequally pinnate, four-paired: leaflets petioled, oblong, acuminate, quite entire, veined, ſmooth above, tomentoſe underneath: the lower leaflets are ſmaller. Flowers white. Panicle corymbed axillary and terminating, much ſhorter than the leaf.

Native of the woods of Guiana, flowering and fruiting in the month of auguſt. The flowers have a ſmell ſweeter than that of the Lilac[m].]

ROBINIA. (*From Jean Robin, arboriſte du Roy, author of* Hiſtoire des Plantes, &c. *Par.* 1620. 12. *printed alſo with the ſecond edition of Linocier's Hiſtory of Plants.*)

——— Yellow: 5 to 9. 13 to 15: in *n.* 9. becoming blood-red.]

1. The common falſe or baſtard Acacia, called in America Locuſt Tree, grows very faſt whilſt young, ſo that in a few years from ſeed, the plants riſe to eight or ten feet high, and it is not uncommon to ſee ſhoots of this tree ſix or eight feet long in one ſummer. The branches are armed with ſtrong crooked thorns. Leaflets eight or ten pairs, ovate, bright green, entire, ſeſſile. The flowers come out from the ſide of the branches in pretty long bunches, hanging down like thoſe of Laburnum: each flower on a ſlender pedicel, white, and ſmelling very ſweet: they appear in june, and when the trees are full of flower, they make a fine appearance and perfume the air round them; but they ſeldom continue more than one week. [Legume oblong, flat, having a longitudinal nerve next the ſeeding future, and on the outſide of that drawn out into a membranaceous margin, one-celled, two-valved. Seeds ſometimes as many as ſixteen, kidney-ſhaped, ending in a hooked beak, compreſſed like a lens, ruſeſcent[o].]

Native of North America, where it grows to a very large ſize, and the wood is much valued for its duration. Moſt of the houſes which were built at Boſton in New England, on the firſt ſettling of the Engliſh, were conſtructed of this timber.

The ſeeds were firſt brought to Paris by Monſ. Robin, from Canada; and ſoon after, we had the ſeeds from Virginia. Many of the trees were raiſed in ſeveral gardens, which for ſome years were in great eſteem, but as they grew larger, their branches were frequently broken by ſtrong winds in the ſummer, which rendered them unſightly, and diſcouraged the introduction of them into ornamental plantations. Great numbers however have been raiſed of late years, ſo that there are now few plantations in which there are not ſome of theſe trees.

The leaves do not come out till late in the ſpring, and fall off early in autumn, which renders this tree leſs valuable in ornamental plantations.

[According to Parkinſon, it was cultivated in England in 1640 by Mr. John Tradeſcant, ſenior[p].

Bradley (in 1720) makes mention of ſome then growing in the Court before Ruſſel-Houſe, Bloomſbury, and in the Old Palace Yard, Weſtminſter[q]. The latter have been long cut down, but the former have been ſeen by every body. They alſo are now (1801) demoliſhed along with the houſe.

The wood, when green, is of a ſoft texture, but becomes very hard when dry. It is as durable as the beſt white Oak, and eſteemed preferable for axle-trees of carriages, trenails for ſhips, and many other mechanic purpoſes. It makes excellent fuel, and its ſhade is leſs injurious to graſs than that of moſt other trees[r]. The leaves afford wholeſome food for cattle. A gentleman in New England ſowed ſeveral acres of it for that purpoſe.

It has been employed with ſucceſs in Virginia for ſhip-building, and found to be far ſuperior to American Oak, Elm, Aſh, &c. for that purpoſe[s]. In New York it has been found upon repeated trial, that poſts for rail-fencing made of this tree, ſtand wet and dry next the ground, better than any other in common uſe; almoſt as well as poſts of the ſwamp Cedar[t].

Sir George Savile planted many thouſands of theſe trees at Rufford; ſo that the next generation will probably be ſufficiently furniſhed with this article of trenails at leaſt. The choiceſt pieces only of the beſt Oak-timber are applied to this purpoſe at preſent; and as the Suſſex Oak is generally reckoned the beſt, moſt ſhipwrights, even in the north, have their trenails from thence, and the demand for them is ſo great, that trenail-making is there become a conſiderable manufacture.

A Locuſt tree in New England, forty years old, was in 1782 ſixty feet high, and four feet ten inches in girt at three feet from the ground[u].

Even in England, ſays Mr. Gilpin, it is often a very beautiful tree, whether it feathers to the ground, or is adorned with a light foliage hanging from the tree; but its beauty is very frail, being of all trees leaſt able to endure the blaſt.

Monſ. L'Heritier mentions a variety very lately introduced into gardens, having no thorns on the branches, which is eaſily known at firſt ſight by its peculiar appearance.]

Mr.

Digitized by Google

Mr. Miller has a variety, which he ſets down for a diſtinct ſpecies, under the name of *Rob. echinata*. The pods are much ſhorter, and cloſely beſet with ſhort prickles, but in other reſpects it agrees with the common ſort. There was a large tree of it in the Biſhop of London's garden at Fulham.

[2. This is a thornleſs tree, growing to the height of thirty feet; very much reſembling the preceding in habit, and dividing into round, almoſt upright, very long branches. Leaves ten inches long, ſcattered alternately over the whole branch: leaflets moſt commonly five on each ſide, ovate, blunt, attenuated at the end, ſhining, quite entire, oppoſite, petioled, two inches long. Racemes axillary. Flowers without ſcent, roſe-coloured. Legumes ſmooth, browniſh.

Native of Carthagena in New Spain, where they uſe it much for hedges to their gardens, but unleſs it be kept down, it will fill the ground by the great quantity of ſeeds which it ſcatters [x]. Found alſo in Hiſpaniola.

3. This is an upright tree without thorns, growing to the height of twelve feet. Leaves alternate, numerous, ſhining; having three leaflets on each ſide, ſometimes two, very ſeldom five; theſe are ovate, blunt, emarginate, entire, petioled, oppoſite, two inches long. Racemes axillary, half a foot in length; pedicels ſhort, two-flowered, numerous. The flowers have the ſmell and colour of Violets [y].]

According to Mr. Miller it riſes to the height of twenty feet, dividing at the top into ſeveral ſpreading branches, which are covered with a very light-gray bark. The leaves are compoſed of eleven pairs of leaflets, which are of a lucid green on the lower part of the branches, but thoſe towards the end are covered with a ſoft ferruginous down. The flowers come out in long bunches fom the ſide of the branches; they are blue, and ſtand upon long foot-ſtalks. Legumes downy. Dr. Houſtoun found it growing naturally at Campeachy; [Jacquin, about Carthagena. It was cultivated before 1759, by Mr. Miller [z].]

4. This riſes in Carolina, where it grows naturally, ſometimes to the height of twenty feet, but in England it ſeems to be of low growth; the branches ſpread out near the ground, and produce their flowers very young. The young branches, and alſo the peduncles and calyxes are cloſely armed with ſmall brown prickles, or rather ſtiff briſtly hairs, like Raſpberries and ſome ſorts of Roſes. The leaves are like thoſe of the firſt ſort, but the leaflets are larger and rounder. The flowers are larger, and of a deep roſe-colour; but they have no ſcent: they come out early in june, and make a fine appearance. Each flower is on a ſhort ſeparate pedicel. Legumes flat oblong.

[Mr. Marſhall ſays, it ſends up weak branching ſtalks, to the height of ſix or eight feet only, but often flowers much ſmaller; that the leaves have five or ſix pairs of oval concave leaflets, with their midribs protruding in ſhort briſtly points; that the flowers are of a peach-bloſſom colour, with the ſtamens diſtinctly in two bodies; whereas thoſe of *R. Pſeudacacia* are frequently all joined at the baſe [a]. It was cultivated by Mr. Miller in 1758 [b].

5. Stem ſhrubby, three feet high, upright, branched. Leaflets ovate-lanceolate, ſmooth, bright green, two or three-paired. Racemes terminating, ſhort. Corolla yellow. Legume oblong, narrowing to each end, ſmooth [c].

Branches round, unarmed. Leaflets five, ovate, ſmooth, quite entire. The racemes have three flowers fixed at each tooth, each on its proper pedicel. Calyx ſubtruncate [d].—Native of the Eaſt Indies, China and Cochinchina [e].

6. Trunks arboreous, commonly branched from the bottom, ſlender, with a ſmooth, ſhining, coriaceous bark, covered by a greeniſh aſh-coloured ſkin: branches alternate, very much divided; twigs rod-like, weak, very leafy, aſh-coloured or greeniſh, with longitudinal nerves running from bud to bud. Buds alternate, frequent, bearing both leaves and flowers, unarmed, with the ſtipules of the bud-leaves ſoft, but in the new branches ſpineſcent, divaricating, rigid. Pairs of leaflets from four to ſix, oblong, ſmooth, quite entire, ſubmucronate with a ſpinule from the nerve; the common petiole grooved above, between the extreme pair ſetaceous and a little prominent. Peduncles from the buds of the branches of the former year, two and three together ſolitary, with a broken joint near the flower. Calyx drooping a little, bell-ſhaped, ſmooth, permanent, five-toothed but not deeply, the upper tooth wider and more diſtant. Corolla larger than the calyx, yellow, having wings as long as the ſtandard, and a keel ſcarcely ſhorter. Legumes cylindrical, rigid, mucronate. Seeds five to eight, oblong, yellowiſh-gray powdered with brown, rather large. The germination is made by the firſt leaves being ternate, and the laſt of the firſt year two or three-paired [f].

Leaves five or ſix-paired. Stipules and point of the petioles ſubſpineſcent, as in the following ſpecies. Flowers ſix, at the bud of the former year, on their proper peduncles [g].]

It riſes with a tree-like ſtem near twenty feet high, ſending out many ſide branches, with leaves compoſed of four or five pairs of oval leaflets, placed oppoſite. Flowers axillary, one on a peduncle. Pods oblong, taper, containing three or four ſeeds.

[Wood hard, compact, very tough, yellow on the outſide, within waved and ſtriped with bay and red. The leaves are good fodder for cattle; and it is ſuggeſted that they contain a blue colouring matter like Indigo. The ſeeds are good for poultry. The bark is very tough, and fit for tying; the twigs may alſo be uſed as withes [h].

Native of Siberia. Cultivated in 1768, by Mr. Miller. It flowers in april and may [i].

7. This reſembles the preceding, but is diſtinguiſhed by its ſtiff or thorny ſtipules. It is a ſhrub above the height of a man. Leaflets ſix or eight, ovate, even. Common petiole woody, the whole of it perennial, thorny at the end. Stipules awl-ſhaped, thorny, perennial [k].

The trunk is ſcarcely an inch and half in diameter, with branches often a fathom in length, ſubdivided, twiſted and diffuſed, ſo as to form a hemiſpherical head, full of branches and thorns. Being covered with flowers during the whole ſummer, it appears very beautiful. Wood bay-coloured within, on the outſide yellow, very hard. Cuticle on the younger branches greeniſh yellow, leſs ſhining and more ſtrigoſe than in *R. pygmæa*, with aſh-coloured longitudinal nerves, running from branch to branch. Branches round, divaricating, alternate. Thorns ſpreading out every way almoſt at right angles, alternate, very large, ariſing from the permanent petioles enlarged, marked alſo with the ſcars of the leaflets, and having at the baſe on each ſide a ſmall, briſtle-ſhaped ſpinule, ſtanding up, and ariſing from the ſtipules. There are ſeveral leaves and two or three flowers from the axils of all the ſpines on the branches. The petioles are ſpineſcent. The leaflets commonly two pairs, but ſometimes three and even four, linear-lanceolate, mucronate at the end with a ſpinule, oppoſite and remote. Peduncles ſo ſhort that the flowers ſeem to be ſeſſile. Calyx angular, ſmooth, five-toothed; the two upper teeth, longer than the others and approximating. Corolla deep yellow, twice as long as the calyx, with an oblong reflex ſtandard, ſcarcely longer than the wings, which are linear. Legumes teſtaceous, cylindrical, very ſtiff. Seeds oval, greeniſh dotted with brown.

On account of the length and toughneſs of the branches, and its large ſtout thorns, this ſhrub is admirably adapted to form impenetrable hedges, and is ſufficiently hardy to bear our climate. It is a native of Siberia, and alſo of China; where, about Pekin, they ſtick the buſhes in clay on the tops of their walls, to prevent perſons from getting or looking over them [l].

Digitized by Google

It was introduced here in 1775, by Hugh Duke of Northumberland; and flowers in april and may[m].

8. This is a ſhrub, ſomewhat thorny, about three feet in height. Root ſparingly branched, having ſomewhat of the ſmell and taſte of Liquorice. Stems upright, ſcarcely branched, round, gray, tubercled: bark bay-coloured, torn: branches alternate, erect, round, like the ſtem: ſhoots ſomewhat angular with three lines running down from the ſtipule, prickly as it were with the ſtipules, putting off the cuticle, of a greeniſh bay-colour. Leaves alternate, petioled, ſpreading, two inches long: leaflets commonly oppoſite, ſubſeſſile, ovate obovate or cuneate, mucronate with a fine point, entire, at firſt pubeſcent but afterwards almoſt naked, one-nerved, the upper ones gradually leſs, bright green, the ſame colour on both ſides, ſpreading, flat. Petioles roundiſh on one ſide, having one ſlight ſtreak on the other, pubeſcent, ending in a ſoft ſpinule. Stipule two-parted, the ſegments lanceolate-linear and ſpreading, becoming ſtiff or thorny, permanent. Flowers axillary, ſolitary, on longer peduncles, ſpreading, yellow. Peduncles ſuberect, filiform, jointed at top, pubeſcent, having an acute little bracte at the joint. Calyx pubeſcent; the teeth almoſt equal, ſharp, the two upper ones approximating. Standard of the corolla oval, emarginate, almoſt upright, reflex at the ſides, larger than the other petals: wings oblong, blunt, creſcent-ſhaped at the baſe, ſtraight, looſe, a little ſhorter than the ſtandard: keel two-petalled, oblong, acuminate, ſcarcely ſhorter than the wings. Legumes linear, roundiſh but flatted a little, acuminate, naked, bay-coloured. Seeds oblong, bay ſomewhat variegated.

It differs from R. Caragana, with which Pallas confounded it, in being of much ſmaller ſtature, in having leaves that are leſs and many-paired, and ſtiffer ſtipules; the flowers are ſolitary, not aggregate, and are produced on the annual ſhoots, not on the branchlets of the year preceding; the legumes are ſlightly compreſſed, not cylindrical as in R. Caragana.—Native of Dauria.

The ſynonyms in Pallas that belong to R. Caragana, the middle figure in his plate, and the former part of his deſcription, are to be omitted here, and referred to that ſpecies[n]. See his whole deſcription there.

9. This is a diffuſed ſmooth ſhrub or underſhrub. Root ſomewhat branched, thicker than the ſtems, having a ſmell approaching to that of Liquorice. Stems upright, round, ſomewhat branched, gray, from a yard to a yard and half in height. Branches alternate, like the ſtem, at firſt upright, then decumbent, with a torn cuticle. Shoots angular with a ſtipule running down in three lines more raiſed than in the other ſpecies, at firſt green, afterwards bay-coloured. Leaves alternate, two-paired: leaflets oppoſite, ſeſſile, remote, the two upper ones larger, obovate, ſcarcely emarginate or rather repand, having a very fine point ſcarcely viſible, entire, one-nerved; the midrib prominent beneath, ſcored above; ſmooth, ſcarcely paler on the under ſurface. Petioles round on one ſide, having one groove on the other, ending in a very ſhort prickle between the uppermoſt pair of leaflets. Stipules ſupporting the petiole, two-parted, linear on each ſide, very ſharp, ſpreading, becoming prickles and permanent. Flowers lateral, ſolitary, ſeldom two together, obliquely peduncled, pendulous, yellow with the diſk of the ſtandard green, becoming afterwards blood-red. Peduncles filiform, at the end jointed and bracted, patulous, continuing a little white after they are fallen off. Bracte very ſmall and ſhort, at the joint. Teeth of the calyx nearly equal, acute, pubeſcent at the edge, upright. Standard of the corolla inverſely oblong or lanceolate, ſubemarginate, ending in a wide channelled claw, the whole reflex: wings oblong, blunt, creſcent-ſhaped at the baſe: keel two-petalled. Legume cylindrical, many-ſeeded.

Native of China, as ſuppoſed, where it has the name of *Chamlagu*[o]. Introduced in 1773, by Monſ. Richard[p].

[m] Hort. kew. [n] L'Heritier. [o] Idem. [p] Hort. kew.

10. Branches round, ſmooth, with a purpliſh-gray bark, leafy only at top, ſcaly below the leaves: branchlets alternate, four-cornered with ovate acuminate imbricate ſcales. Leaves alternate, diſtant, from the end of the branchlets or a little below, ſolitary or two or three together, all petioled, nine-paired: leaflets on very ſhort petioles, alternate, the outmoſt a little ſmaller; all oval or roundiſh, ſmooth on both ſides, ſhining, ſimply veined, ſubretuſe, the midrib beyond the leaflet running out into a ſpine. Petiole unarmed. Stipules rigid, thorny, from upright-ſpreading, permanent. Peduncles axillary, ſolitary, filiform, pubeſcent, ſhorter than the leaf. Pedicels four or five, diſtant, jointed below the flower. Bracte ſmall, linear, at the baſe of the pedicels. Calyx ſmooth, with lanceolate ſegments. Legume compreſſed, linear, ſtraight, acute, jointed or contracted between the ſeeds, which are from two to five.—Native of the iſland of St. Thomas in America.

11. This is a very handſome ſhrub, leafleſs in the time of flowering, when it is quite covered with flowers. Branches round, ſmooth, purpliſh-aſh-colour, ſmooth. Lower leaves from the bud of the former year after the fall of the flowers, commonly two or three, approximating, a finger's length; at top and on the younger branches ſolitary, alternate, more remote; on the lower ones longer by half, with leaflets hardly an inch in length: all petioled, alternate. Leaflets on ſhort petioles, oppoſite, ſmooth, oblong, veined, mucronate, the inner ones a little ſmaller. Petiole unarmed. Stipules lanceolate, ſmall, attenuated, unarmed, flexile, permanent. Peduncles four or five from each bud, capillary, one-flowered, jointed below the flower. Calyx goblet-ſhaped, ſmooth, with the margin entire, villoſe when magnified. Corolla large, purpliſh, with the claws of the petals of the ſame length with the calyx. Germ ſmooth.—Native of America, in Krabben Iſland[q].

12. This is a ſmall tree or ſhrub, commonly the height of a man, irregular, very much branched, rigid, leafy only at the ends of the branches, ſtouter than *R. fruteſcens*, with a ſtrigoſe gray bark. Branches ſubflexuoſe, alternate, the extreme ones ſtriated; the petioles, when old, become thorns, and are ſcattered alternately. Branchlets and leaves from the axils of the ſpines. Leaflets obovate-oblong, hoary with a very fine nap, mucronate with a ſpinule; the common petiole is ſpineſcent. Stipules at the baſe of the petioles, very ſmall, ſoft. Sometimes two-paired and three-paired leaves are ſeen on the ſame ſhrub. Flowers on the upper branches copious, in racemes commonly of three, but ſometimes only of two flowers, purpliſh, almoſt the colour of Lathyrus tuberoſus, ſmelling ſweet. Calyx five-toothed, with two of the teeth approximating: ſtandard nearly equal to the wings and keel: all the petals whitiſh at the baſe. The corolla in many flowers, and frequently all on a ſhrub, ſix-petalled, the wings being doubled. Each pedicel has a ſtipule. The peduncles with the permanent calyx are hoary. Legumes ſhort, inflated, hard, remaining on to another year. Seeds reniform-ſubglobular, of a yellowiſh gray colour[r].

The whole of this ſhrub is ſilky. It has all the habit of a *Robinia*, but a pedicelled germ, and an inflated legume, like that of *Phaca* or *Colutea*[s].

Native of Siberia, in dry naked ſalt fields by the river Irtis; flowering in june, and highly agreeable to many inſects, eſpecially of the genus Meloe, many ſpecies of which are peculiar to this region. It flouriſhes in gardens, but has never produced flowers in them, probably for want of the ſaline principle in the ſoil. As it is a handſome ſhrub, this is to be lamented[t]. It was introduced here in 1779, by William Pitcairn, M. D.[u]

13. Trunk branched from the bottom, with a duſky or greeniſh-aſh-coloured bark; there are commonly many lateral ſhoots or ſuckers from the root. Branches rod-like, pliant, loaded with leaves and flowers, of a ſhining yellowiſh colour, with longitudinal gray nerves,

[q] Vahl. [r] Pallas. [s] L'Heritier. [t] Pallas. [u] Hort. kew.

Digitized by Google

with triple ſpines. Leaves on the ſhoots of the year alternate, with ſpineſcent ſtipules; from the buds in bundles, with unarmed ſtipules. Leaflets cluſtered, obovate, attenuated at the baſe, with a ſpinule at the end: petiole ſpineſcent, after the leaves are fallen, hardening with the ſtipules into a triple ſpine. Peduncles on the branches of the preceding year, from each bud, one, two or three, bent a little at the joint, one-flowered. Calyx, like the whole plant, ſmooth, permanent, ſhortly bell-ſhaped, deeply four-toothed; the teeth ſubciliate, the upper one larger and more remote. Corolla frequently drooping topſy-turvy, three times as large as the calyx, yellow: ſtandard reflex; wings with the keel biggiſh, oblong, entire. Legumes cylindrical, of a teſtaceous-gray colour and hard. Seeds oval, gray [x].]

It grows with a ſhrubby ſtalk eight or ten feet high, ſending out ſeveral branches which grow erect, covered with a ſmooth yellowiſh bark. The leaves have two pairs of oval pointed leaflets, on ſhort foot-ſtalks. The flowers are produced upon ſingle peduncles, which come out at the joints of the branches: they are yellow, ſhaped like thoſe of Laburnum, but ſmaller, appear in may, and if the plants ſtand in a moiſt ſoil and ſhady ſituation, the ſeeds will ripen at the end of auguſt.

[Native of Siberia, by the Volga, &c. in temperate ſituations, on hills and the rocky banks of the river [y]. Cultivated in 1759, by Mr. Miller [z].

14. Trunks covered with a ſhining yellowiſh bark. Wood of a very deep bay, almoſt as hard as horn: the older twigs round, with a beautifully golden ſhining cuticle; branchlets gray, with very frequent two-ſpined buds. Spinules ſlender like needles, ſpreading, ariſing from the ſtipules, in the older branches deciduous. Leaflets four or ſix in the ſpontaneous ſhrub cluſtered in bundles, quite ſeſſile, linear acuminate, a little hiſpid. Peduncles ſpringing ſingly from moſt of the buds on the branchlets among the leaves, the length of the leaflets, bent at the joint. Calyx ſomewhat hairy, five-toothed, the two upper teeth approximating. Corolla twice the ſize of the calyx, deep yellow: ſtandard ovate, compreſſed, tawny at the back; wings wide-lanceolate, equal to the ſtandard; keel a little ſhorter. Legumes round flatted a little, rigid, mucronate. Seeds partly ovate, partly oblong, yellowiſh powdered more or leſs with black dots.

The Altaic plant is ſcarcely a ſpan high, more branched, with more remarkable ſpines, but with ſlender leaves and ſmaller flowers. In the gardens, the leaves are more remarkable, being four in form of a ſtar, on a large ſpreading petiolar ſpine; there is a third acceſſory pair at the very baſe of the ſpine, ſpringing out between the ſtipular ſpines. The firſt leaves of the ſeminal plant are ternate [a]. That Linneus ſays is the caſe in all the Siberian ſpecies. He remarks, that this reſembles the preceding very much, but is of a dwarf ſtature and more thorny; that the leaves are wedge-ſhaped, very blunt, and hardiſh; and that the ſtipules in the primordial leaves are leafy and lanceolate in this ſpecies only.]

It is a weak low ſhrub, ſeldom riſing more than three feet high in England: the branches are ſlender, and are covered with a light bark. The leaves are compoſed of four oblong ſeſſile leaflets: the flowers are produced ſingly upon axillary peduncles; they are yellow and appear in april, but are rarely ſucceeded by ſeeds in England.

[Native of Siberia; where this elegant ſpecies begins by the Irtis, in the ſouthern, rocky, open parts; becomes more frequent by the Jeniſea; and moſt common in the regions beyond the lake Baikal. It riſes commonly with twigs an ell in height where it is expoſed to the firing of the country in ſpring; but in the mountains it grows with a trunk the height of a man, and the thickneſs of his wriſt. The twigs are very tough and fit for withes; and are of an elegant golden colour [b]. Mr. Miller cultivated it before 1768 [c].

[x] Pallas. [y] Idem. [z] Hort. kew. [a] Pallas.
[b] Idem. [c] Hort. kew.

15. This is a ſhrub about a fathom in height. Root branched, having the ſmell and taſte of Liquorice. Stem upright, ſomewhat branched, round, tubercled, gray: branches alternate, ſpreading, like the ſtem. Leaves alternate, ſpreading, eight inches long. Leaflets from twelve to fifteen pairs, oppoſite, on ſhort petioles, thoſe of the outmoſt longer, oblong, blunt and ſcarcely acuminate, quite entire, one-nerved; the midrib prominent below, the veins ſcarcely apparent; almoſt naked, bright green, paler underneath, ſpreading very much, flat, from twelve to eighteen lines long, from ſix to eight lines wide. Petioles round on one ſide, channelled on the other; both theſe and the petiolets pubeſcent. Stipules linear, acute, pubeſcent, browniſh, upright, permanent. Racemes axillary, ſolitary, peduncled, patulous, bracted, pubeſcent, four or five inches long. Flowers alternate, nodding, pedicelled, yellow. Pedicels round, jointed at the top. Bractes lanceolate, acute, concave, preſſed cloſe, pubeſcent, brown. Calyx half-four-cleft, pubeſcent; ſegments lanceolate, acute, upright, the upper one double the width of the reſt and bifid. Corolla longer than the calyx: ſtandard obcordate, wholly bent back; wings oblong, blunt, appendicled and creſcent-ſhaped below: keel two-petalled, oblong, acute, compreſſed, of the ſame ſhape with the wings. Filaments ſcarcely united at the baſe. Germ pedicelled. Stigma blunt. Legume oblong, narrowing into a pedicel, acuminate, compreſſed. Seeds few (about three) oblong, almoſt kidney-ſhaped, ſmooth.

It recedes a little from its congeners in having all the filaments united together at the baſe only, and in having a pedicelled germ. It has the leafing of the firſt ſpecies, but the branches have no thorns. The ſtigma is naked, not villoſe, as in *R. Pſeudacacia* and *biſpida*.

Native of Abyſſinia; whence the ſeeds were brought by Bruce, and introduced into the Paris garden, with many other plants of that country [d].

16. This is a ſhrubby plant, four feet high, without any thorns: branches diffuſed, of a reddiſh brown colour. Leaflets about five pairs, ovate-oblong, greeniſh-brown above, whitiſh underneath. Racemes upright, long, ſubterminating. Calyx flattiſh, four-toothed. Corollas violet: ſtandard roundiſh, ſpreading; wings oblong, ſtraight; keel ſhorter, blunt, one-leafed. Legume long, roundiſh, ſtraight, acuminate, ſmooth; containing many oblong-reniform ſeeds. Root ſomewhat fleſhy, of a yellowiſh-brown colour, and very bitter.—Native of China and Cochinchina.

17. This alſo is a ſhrubby plant, but only one foot high. Leaves upright. Leaflets ſeven or eight-paired, oblong, ſubacute, ſmooth, pale green. Flowers white, terminating; with peduncles in threes, upright, and three-flowered. Root ſimple, woody, thick, yellow, bitter.—Native of the northern provinces of China [e].]

PROPAGATION AND CULTURE.

1. Falſe or Baſtard Acacia or Locuſt-tree is generally propagated in the Engliſh nurſeries, by ſuckers from the roots of the old trees; or by cutting off ſome of the roots, and planting them upon a gentle hot-bed. But theſe are not ſo valuable as plants raiſed from ſeeds; becauſe they do not make ſo great progreſs, and are very ſubject to ſend forth many ſuckers.

Sow the ſeeds on a bed of light earth at the end of march or beginning of april. If the bed be well expoſed to the ſun, the plants will appear in five or ſix weeks, and will require no farther care but to keep them clear from weeds. The following ſpring, about the end of march, tranſplant them into a nurſery, in rows three feet diſtant, and a foot and half aſunder in the rows. After two years more they will be fit to tranſplant where they are deſigned to grow: for as they ſend forth long tough roots, if they ſtand long unremoved, the roots will be cut off, when they are tranſplanted, which ſometimes occaſions their miſcarrying.

[d] L'Heritier. [e] Loureiro.

This

Digitized by Google

This tree will grow well upon almoſt any ſoil, but beſt in ſuch as is light and ſandy; where it will ſhoot ſix or eight feet in a year. Whilſt young and well furniſhed with leaves it makes an agreeable appearance; but when old, the branches being frequently broken by winds, it is rendered unſightly, eſpecially in an expoſed ſituation.

[In New England, the Locuſt tree is increaſed not only by ſeeds and ſuckers, but alſo by ſets, as we do Willows; but they get the largeſt trees from ſeed.]

4. The Roſe-Acacia, as it is commonly called, not producing ſeeds in England, is propagated by cutting off part of the roots, and planting them upon a gentle hot-bed, where they will put out fibres and ſhoots. It ſhould have a ſheltered ſituation, and a light moiſt ſoil. Though the ordinary winters of this country never injure it, yet in very ſevere ſeaſons the young plants are ſometimes killed in expoſed places. [Their branches are alſo liable to be broken by high winds. Marſhall, in his *Arbuſtum Americanum*, deſcribes it as ſpreading much from its running roots; but it does not do ſo in any great degree here. It may be increaſed by layers, and by grafting. It is of a ready growth, diſpoſed to flower even when young, and not nice as to ſoil or ſituation. On account of its large, beautiful branches of roſe-coloured flowers, it is one of the moſt valuable ſhrubs we have for ornamental plantations [f].]

6. 7. 8. 9. 12. 13. 14. The Siberian ſorts are propagated from ſeeds ſown in a ſhady ſituation in autumn; and then the plants will come up the following ſpring: but if the ſeeds are ſown in the ſpring, the plants ſeldom riſe the ſame ſeaſon. When the plants come up, they will require no other care but to keep them clean from weeds till autumn; when, if they have made any progreſs, they ſhould be planted on a north border, at about ſix inches diſtance, where they may grow two years, and then be planted out where they are to remain, which ſhould be in a cool moiſt ſoil, not too much expoſed to the ſun. [They may alſo be increaſed by the roots, by layers and grafting.]

2. 3. 5. 10. 11. 15. Being tender, cannot be maintained in England, unleſs they are placed in a ſtove in winter. Theſe are propagated by ſeeds procured from the countries where they grow naturally. Sow them in ſmall pots filled with earth from the kitchen garden, and plunged into a hot-bed of tanner's bark. The plants will appear in ſix weeks or two months. When theſe are fit to tranſplant, ſhake them out of the pots, and put each plant into a ſmall pot filled with the like earth, and plunged into the tan-bed; ſhading them till they have taken new root, and then treating them as other tender plants.

Whilſt the plants are young they are more tender than afterwards; therefore it will be proper to keep them in the tan-bed for two or three years: but when they have obtained ſtrength, they may be kept in a dry ſtove of a temperate heat in winter: and in ſummer they may be expoſed to the open air in a ſheltered ſituation. Some of the ſorts may be propagated by cuttings. [The 15th ſometimes ripens its ſeeds in France [g].

Leaves ovate emarginate.

DESCRIPTIONS, *&c.*

1. This is a ſhrub, three or four feet high, with a branching, upright, unarmed ſtem: branches ſubdivided, flexuoſe, round, thorny, almoſt even, covered with an aſh-coloured bark. Thorns near the baſe of the petioles, ſolitary, ſtretched out, three times ſhorter than the petioles. Leaves in bundles, or threes, ſeldom more, alternately cluſtered, on ſhort petioles, ſometimes emarginate, ſmooth on both ſides, browniſh-green, paler underneath, ſlightly nerved, ſomewhat rigid. Peduncles commonly terminating, axillary, ſubdichotomous, cluſtered, cymed, ſhorter than the leaves. Flowers ſmall, greeniſh or whitiſh: ſegments of the calyx upright, pubeſcent: tube of the corolla five-cornered. Germ villoſe: ſtyles ſhorter than the filaments, villoſe: ſtigmas villoſe, ſubplumoſe.—Native of Jamaica, on dry rocky mountains.

DESCRIPTIONS, *&c.*

1. This is a low ſhrubby plant, ſomewhat like a heath when not in flower. The narrow ciliate leaves are cluſtered about the flower-bud like bractes. A ſingle flower terminates each branch, differing from that of the Campanula, to which it is very nearly related, in being funnel-ſhaped, that is having a tube, and a border ſpreading out; whereas in Campanula, the corolla is bell-ſhaped, or ſpreads gradually from the bottom.—When a flower is recently expanded, five ſhades of colour appear, which being diſpoſed in circles, produce a ſtriking effect: the bottom of the flower is white, of a yellowiſh caſt, next ſucceeds a circle of deep blue inclining to black, with a ſurface highly glazed, the next circle is greyiſh-blue reſembling ſatin, the next nearly white, and the outermoſt pale purple. The anthers at firſt are cloſely applied to the ſurface of the corolla, and reſemble ſo many ſmall ridges; the ſtigma, as in many other flowers, does not aſſume its true appearance till the corolla is on the decay; then it becomes bifid [k]. Capſule ovate-cylindrical, crowned with the pinnate-toothed rigid leaflets of the calyx; and within theſe, by five ſcalelets of the ſtamens, united at the baſe into a hemiſpherical cup. Seeds ſubovate, angular, rugged with raiſed dots, or ſhagreened as it were, ferruginous, faſtened to the branchlets of very ſlender threads hanging down from the top of the capſule [l]. Gærtner could not diſtinguiſh any veſtige of a partition in ripe capſules.

Native of the Cape of Good Hope and Barbary.—It was introduced by Mr. Francis Maſſon in 1774 [m]: but it was long before known to Dutch botaniſts. It flowers in june, and continues ſeveral weeks [n].

2. Native of the Cape of Good Hope, where it was found by Thunberg.—Maſſon alſo introduced it from thence in 1787. It flowers in june [o].

3. This differs from the two preceding in being annual. It is a native of the Cape, like the others, and was introduced by Maſſon in 1787. It flowers in ſeptember [p].

4. This is a very ſmall plant, annual, herbaecous and diffuſed, reſembling a moſs when not in flower.—Thunberg found it at the Cape.

5. This is ſhrubby and upright. The flowers are not ſolitary, but aggregate; forming a ſort of ſpike.—Found at the Cape by Thunberg [q].

PROPAGATION AND CULTURE.

The firſt, and other ſhrubby ſpecies may be increaſed by cuttings, but not very readily. They are not ſo eaſy of culture as many others. They muſt be kept in a dry ſtove, good green-houſe or glaſs caſe.

Roella reticulata is *Gorteria ciliaris.*

ROHRIA. (*So named by Schreber, in honour of Julius von Rohr, who travelled into America, and ſent many plants to Europe from Surinam, Carthagena, St. Martha, Cayenne, Jamaica, Martinico and other iſlands of the Weſt Indies, which are edited by Vahl.*)

Lin. gen. Schreb. n. 63. Tapura. *Aubl. t.* 48. *Juſſ.* 419.

Claſſ. 3. 1. Triandria Monogynia.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, bell-ſhaped, five-parted: *ſegments* ovate, concave, blunt, ciliate, coriaceous; the two inner ones a little longer.

COR. *Petals* five, upright, longer than the calyx, the two upper ones a little larger, the three lower ſmaller: *claws* narrow, wider at the baſe, woolly within, under the laminæ a little bent outwards: *laminæ* ovate, erect, in the larger petals bent inwards and cowled, in the ſmaller ſpread out and bluntiſh.

STAM. *Filaments* three, one between the two larger petals, and two by the ſide of them, united at bottom with their claws, filiform, longer than the corolla, woolly within. *Anthers* roundiſh, erect, with the face turned inwards.

PIST. *Germ* turbinate, tomentoſe. *Style* filiform, the length of the ſtamens, villoſe. *Stigmas* three, revolute.

Echinops fruticoſus. *Lin. ſpec. ed.* 1.
E. fruteſcens ad nodos floridus. *Plum. ic.* 114. *t.* 123.
Amaranthoides fruticoſum, &c. *Sloan. jam.* 1. 43. *t.* 7. *f.* 3.

DESCRIPTION, *&c.*

Stem ſtraight, woody, covered with a ſmooth reddiſh-brown bark; having at every inch or two one, two or three leaves, greater and ſmaller, the largeſt about two inches long, and three quarters of an inch broad in the middle, ſmooth, dark green on the upper ſide, and very white underneath, on a very ſhort foot-ſtalk. At each axil a ſeſſile conglomerate head of flowers[s].

Native of the Weſt Indies.

ROMULEA. See *Ixia Bulbocodium.*
RONABEA. See *Pſychotria.*]
RONDELETIA. (*So named by Plumier, in memory of Guilleaume Rondelet, a famous phyſician and natural hiſtorian of Montpelier.*)
Lin. gen. n. 224. *Reich. n.* 240. *Schreb. n.* 296. *Plum.* 12. *Juſſ.* 201.
Claſſ. 5. 1. Pentandria Monogynia.
Nat. order of *Rubiaceæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, ſuperior, five-parted, acute, permanent.
COR. one-petalled, funnel-ſhaped: *tube* cylindrical, longer than the calyx, bellying a little at top: *border* five-parted, from reflex flat; ſegments roundiſh.

[r] Willdenow. [s] Sloane.

STAM. *Filaments* five, awl-ſhaped, almoſt the length of the corolla. *Anthers* ſimple.
PIST. *Germ* roundiſh, inferior. *Style* filiform, the length of the corolla. *Stigma* bifid.
PER. *Capſule* roundiſh, crowned, two-celled.
SEEDS ſeveral, or ſometimes ſolitary.
OBS. *Several of the ſpecies have four parts in the fructification.*

ESSENTIAL CHARACTER.

Cor. funnel-ſhaped. *Capſ.* two-celled, inferior, many-ſeeded, (or with one or two ſeeds only) roundiſh, crowned.

SPECIES.

* *With many ſeeds.*

1. Rondeletia americana.
Lin. ſpec. 243. *Reich.* 1. 473. *Willd.* 930.
R. arboreſcens tini facie. *Plum. gen.* 15. *ic.* 142. *f.* 1.
Leaves ſeſſile, panicle dichotomous.

[2. Rondeletia odorata.
Lin. ſpec. 1671. *Willd.* 930. *Jacqu. amer.* 59. *t.* 42. *pict.* 34. *t.* 61. *Swartz, obſ* 67.
R. obovata. *Lin. ſyſt.* 212. *Reich.* 1. 474.
Leaves petioled ſubovate blunt.

3. Rondeletia trifoliata.

13. Rondeletia hirta.
Lin. ſpec. ed. Willd. 933. *Swartz, prodr.* 41. *deſcr.* 373. *Ait. kew.* 1. 227.
Leaves oblong acuminate rough-haired rigid nerved underneath, peduncles axillary trichotomous erect.

14. Rondeletia buxifolia.
Vahl, ecl. 2. 11.
Leaves obovate ſmooth, flowers four-ſtamened axillary ſolitary.]

DESCRIPTIONS, *&c.*

1. This riſes with a woody ſtalk ten or twelve feet high, branching out on every ſide; the branches covered with a ſmooth greeniſh bark. Leaves oblong, ending in acute points, entire, the upper ſurface lucid green, the under pale; they are a little crumpled, and ſtand alternate. The flowers come out in bunches at the end of the branches, are white, and have little ſcent. They appear in autumn, but are not followed by ſeeds in England.

[The leaves of this ſmall tree are oppoſite, lanceolate. Common peduncles ſolitary, very long, naked, forming at the top a dichotomous corymb, in each diviſion of which is a ſeſſile flower, with a two-leaved involucre [t].]

The ſeeds of this plant were firſt ſent to Mr. Philip Miller by Mr. Robert Millar, who collected them on the north ſide of the iſland of Jamaica; he alſo obſerved the trees growing plentifully in the Spaniſh Weſt Indies; Mr. Philip Miller alſo afterwards received the ſeeds from Barbadoes, which ſucceeded in the Chelſea garden. [It appears from the 5th edition of his Dictionary, that he cultivated it in 1748 [u].

2. This is an inelegant, irregular, upright ſhrub, five or ſix feet high. Branches round, the younger ones villoſe. Leaves oppoſite, ſubcordate at the baſe, entire, ſomewhat rugged on the upper ſurface, veined and rigid, on very ſhort petioles. Stipules within the petioles, wide, acute. Common peduncles erect, terminating, in threes, three-flowered, the middle diviſion ſometimes ſubdivided into three others that are ſimilar: the pedicels collecting the flowers into a handſome umbel, or umbelled-cyme. Flowers handſome, ſcarlet with the projecting rim of the tube orange-coloured, ſmelling very ſweet like violets. The corolla is very often ſix-parted, with a ſix-leaved calyx, though it has always five ſtamens. The capſules have many angular ſeeds [x].

Native of the Weſt Indies, but not very common. Jacquin obſerved it, at the Havannah, in rocky coppices near the coaſt, growing frequently on the very naked rocks; flowering in january, and at the ſame time loaded with ripe fruit.

By miſtake, the trivial name was printed *obovata* in all the editions of the Syſtema vegetabilium.

3. This is an upright tree, twelve feet in height. The younger branches are obtuſely triangular and hirſute. Leaves lanceolate, acute, quite entire, ſmooth on the upper, ſlightly tomentoſe on the lower ſurface, three inches long, on hirſute petioles. Stipules roundiſh-acuminate, in threes, alternating with the leaves. Racemes hirſute, unequal, branched, axillary, an inch and half in length. Flowers ſmall, reddiſh, ſeſſile and peduncled, void of ſcent. Fruit two-valved, with the partition oppoſite to the valves [y].

Linneus remarks, that the peduncles are ſhorter than the leaves, not longer as in Plumier's plant.

Native of America. Jacquin obſerved it in Jamaica, flowering in february.

4. This is a ſhrub, a fathom in height, with very long, alternately ſpreading, unarmed branches, with a rugged bark. Leaves oppoſite, half an inch long, cordate, in others roundiſh or ovate, entire, ſubreflex, veined, paler underneath, quite ſmooth, on very ſhort petioles. Stipules between the petioles, ſmall, acute. Peduncles axillary and terminating, oppoſite, elongated, upright, having a pair or two of leaves, three-parted, or terminating only three-flowered and leafleſs. Flowers terminating, ſubſeſſile, or ſometimes on very ſhort pedicels, upright, duſky-purple, ſilky-pubeſcent on the outſide. Bractes very ſmall, linear, two or four, under the flowers. Calyx four-leaved: leaflets linear, upright. Corolla ſalver-ſhaped: tube filiform, widening a little at top; border four-parted; ſegments convex, with a yellow notched ring placed on the aperture. Filaments four, very ſhort, in the middle of the tube: anthers linear, ſtriated, yellow. Style longer than the ſtamens, awl-ſhaped. Stigma below the ring of the aperture bifid; ſegments obtuſe. Capſule ſubdidymous, hoary-pubeſcent, crowned with the calyx, two-celled, two-valved, with the partition contrary. Seeds very many, acuminate, compreſſed, ſmall, brown, inſerted or faſtened to their proper ovate receptacle in each cell.

Native of Hiſpaniola, in maritime coppices towards the north, near Cul de ſac, flowering and fruiting in december.

5. This is a ſhrub with round or four-cornered branches, leafy towards the top, and hairy, below even, aſh-coloured, often warted with the old deciduous petioles. Leaves oppoſite, two or three inches long, the upper or terminating ones cluſtered, ovate-lanceolate, entire, nerved, hairy, underneath rough-haired or tomentoſe-hoary. Petioles ſhort, villoſe. Stipules between the petioles, ſubconnate, acuminate, hairy. Peduncles oppoſite, filiform, hairy, at the top trifid or three-flowered; the flowers pedicelled; the lateral pedicels half an inch long, the middle one ſhorter. Bractes two awl-ſhaped at the baſe of the lateral pedicels; and two others at the baſe of the germ, ſhorter by half than the calyx. Calyx four-parted: ſegments lanceolate-linear, acute, villoſe. Corolla ſalver-ſhaped: tube ſubcylindrical, the length of the calycine ſegments, wider at top, on the outſide villoſe or ſomewhat ſilky: border near the aperture crowned with a margined ring, four-parted, with the ſegments roundiſh, ſpreading, convex above, ſhorter than the tube. Filaments four, very ſhort, inſerted in the tube above the middle: anthers oblong, linear, included. Germ villoſe: ſtyle the length of the tube: ſegments of the ſtigma linear, blunt. Capſule ſmall, ſubglobular, twin, villoſe, two-valved with the partition contrary. Seeds numerous, brown.

Native of the Weſt Indies, in the iſlands of Santa Cruz and Montſerrat [z].

Vahl thus deſcribes his *R. triflora*: Branches round, ſmooth below, hairy at top. Leaves at the top of the branches, on ſhort villoſe petioles, oppoſite, the uppermoſt in cluſters, two or three inches long, broad-lanceolate, a little narrowed towards the baſe, acuminate, quite entire, above marked with lines along the nerves, and having hairs thinly ſcattered about, underneath a little hoary wirh frequent longer hairs, ſoft eſpecially the younger ones, nerved. On each ſide an oblong, acuminate ſtipule, ſomewhat villoſe. Peduncles axillary, oppoſite, two inches long, filiform, three-flowered; the fruiting ones an inch and half long and more. Flowers pedicelled: the middle pedicel ſhorter, without any bracte; the lateral ones longer, with a ſubulate bracte on each ſide; at the baſe of the pedicels and above are two others ſimilar on each lateral pedicel. Calyx four-parted; the ſegments awl-ſhaped, villoſe. Corolla one-petalled, cinereous-villoſe on the outſide: tube filiform, widening a little at top, with the ſegments of the border oblong, blunt. Filaments four, very ſhort, inſerted into the tube above. Anthers linear, within the tube. Germ globular, villoſe-cinereous. Style linear, thickened towards the top, villoſe at the baſe. Stigma blunt. Capſule the ſize of black Pepper, globular, villoſe, crowned with the calyx, two-celled, containing many ſeeds.

6. This is a ſmall tree or ſhrub ſix feet high, branched, upright, even, with an aſh-coloured bark. Branches ſimple, almoſt upright, long, ſpreading, round or bluntly four-cornered, ſmooth. Leaves oppoſite decuſſated, three inches long, entire, nerved and veined, on petioles an inch long, ſtriated, ſpreading. Stipules between and above the petioles, preſſed to the branchlet, wide, ovate, acute, ſmooth, rigid. Thyrſes ſolitary oppoſite, ſhorter than the leaves, ob-

[t] Linn. [u] Hort. kew. [x] Jacquin and Swartz. [y] Jacquin. [z] Swartz.

long

Digitized by Google

long, ſpreading; on a common petiole, an inch in length, angular, ſtriated, ſmooth; branchlets oppoſite, decuſſated, ſubdivided; the outmoſt commonly three-flowered. Flowers ſmall, dull, whitiſh-yellow or ferruginous. Bractes ſmall, awl-ſhaped, or little leaflets under the ramifications of the thyrſe. Calyx very minute, five-toothed. Tube of the corolla elongated, cylindrical, ſwelling below the border, ſilky-pubeſcent on the outſide: border five-parted; ſegments roundiſh, convex, diſtant, patulous, with a ſmall ring contracting and crowning the aperture. Filaments five, inſerted into the upper part of the tube: anthers very ſmall, ovate, pale, placed in the very aperture. Germ roundiſh: ſtyle awl-ſhaped, bifid at the top: ſtigmas ſimple. Capſule roundiſh, with a groove along the middle, the ſize of a Coriander ſeed, crowned with the very ſmall calyx, two-celled; having two angular-rounded, ſtriated ſeeds in each cell.

Native of the drieſt hills of Jamaica, in the weſtern part of the iſland; flowering in may: the flowers ſmell very ſweet during the night.

7. This is a ſhrub with round ſpreading branches, covered with an irregular hoary bark: branchlets four-cornered, compreſſed a little at the tip, ſmooth. Leaves decuſſated, quite entire, ſcarcely nerved, veined, ſomewhat membranaceous. Petioles longiſh, four-cornered, ſmooth. Stipules interpetiolary, oppoſite, patulous, convex, wide, very minutely villoſe at the edge. Racemes ſolitary, oppoſite, from upright ſpreading, ſhorter than the leaves: common peduncle the length of the petioles, compreſſed; branches decuſſated, almoſt horizontal, with ſeſſile awl-ſhaped ſpreading bractes every where at the ſubdiviſions of the raceme; flowers pedicelled, diſtinct not cluſtered. Calyx ſmall, with five very ſhort upright teeth. Corolla ſmall, ſilky-hoary on the outſide, pale within: tube ſhort, oblong, equal; border five-parted, ſegments ovate, ſpreading, pubeſcent; aperture naked, five-cornered. Filaments from the middle of the tube: anthers oblong, yellowiſh in the aperture of the tube. Germ ovate, ſmooth: ſtyle ſimple, upright, the length of the tube: ſtigma thickiſh, with the apex more acute and undivided. Capſule ovate, crowned with the calyx, ſmooth, two-celled? opening by two valves, two-ſeeded. Seeds convex on one ſide, flat on the other, joined at the middle, diſtinct from the partition at the ſides. Beſides the ripening ſeeds there are other very minute embryos within the valves.—Native of Jamaica, on the mountains.

It is allied both to *R. thyrſoidea* and *laurifolia*, but differs in the leaves, ſpreading racemes, and flowers.

Browne's figure agrees very well with this plant. In his ſpecific character he makes the leaves verticillate-ternate, whereas in the figure they are oppoſite. He alſo ſpeaks of the flowers as four-ſtamened, which they very ſeldom are.

8. This is a ſhrub, with round, ſmooth, ſomewhat ſtriated branches, jointed as it were with the deciduous petioles, compreſſed a little at the top. Leaves oppoſite, three or four inches long, decuſſated, acuminate at both ends, entire, nerved and veined, paler underneath; on petioles an inch long, roundiſh, flat above, ſmooth. Stipules between the petioles, wide connate acuminate ſpreading rigid ſmooth, except at the edge where they are villoſe. Racemes often the length of the leaves, oppoſite: branches decuſſated, compreſſed a little: pedicels ſcattered, the laſt commonly three-flowered. Bractes minute, awl-ſhaped, at the diviſions of the raceme. Flowers ſmall, duſky-yellow. Calyx five-toothed, very ſmall, pubeſcent: teeth acute, erect, very ſmall. Tube of the corolla very ſhort, ſcarcely longer than the teeth of the calyx, wider under the the border; which is five-parted, with the ſegments the length of the tube, oblong, reflex, tomentoſe above: throat open, with the margin five-cornered, ſmooth, ſhining. Filaments from the middle of the tube, ſhorter than the tube: anthers in the throat, oblong, yellow. Style thickiſh, the length of the tube: ſtigma above the border thickened, bifid. Capſule globular, ſcarcely larger than a ſeed of hemp, ſmooth, crowned with a very minute calyx, two-celled, two-valved; partition contrary. Seeds very many, membranaceous, but two only ripening, and theſe hemiſpherical.—Native of Jamaica.

It is very like R. thyrſoidea, but has the leaves a little narrower and ſmooth on both ſides; the racemes are erect; the tube is very ſhort, not four times as long as the calyx; and two ſeeds only ripen in the capſule. It ſeems to be Browne's plant, though Linneus refers that to his Peteſia ſtipularis; which it can hardly be; becauſe in that caſe, the leaves ought to be tomentoſe underneath, and the flowers thyrſoid.

9. This ſhrub is three feet high, upright, branched above, even: branches and branchlets oppoſite, round, upright, ſomewhat villoſe at the top. Leaves on ſhort pubeſcent petioles, oppoſite, entire, nerved and veined, rough-haired, duſky green, villoſe-tomentoſe underneath, becoming hoary. Stipules between the petioles, ovate with a ſhort point, pubeſcent. Peduncles ſmall, ſeveral times ſhorter than the leaves, three-parted with three-flowered branchlets: flowers ſmall, whitiſh or duſky yellow, villoſe on the outſide. Calyx five-toothed, ſmall. Tube of the corolla longer than the calyx, narrow: border five-parted, with ovate concave ſegments: aperture crowned with a ſmall ring. Anthers within the aperture. Style bifid at the top. Capſule roundiſh, two-celled, ſmall, the ſize of a Coriander ſeed. Seeds ſolitary, hemiſpherical.

Native of Jamaica, on rocky hills; as in Sixteen-mile walk near Spaniſh Town.

It differs from R. thyrſoidea in being ſmaller, in having the leaves pubeſcent on both ſides and tomentoſe underneath, and the racemes flowers and fruit very ſmall.

Peteſia ſtipularis, *ſyſt. veg.* belongs either to this or *R. thyrſoidea:* that ſpecies therefore in our Dictionary is to be blotted out.

P. tomentoſa, *ſyſt. veg.* is certainly a different plant; for Jacquin has deſcribed it as having flowers in corymbs.

10. This ſhrub is two feet high and more, branched and upright: branches almoſt upright, ſubdivided, compreſſed a little, even: branchlets hirſute at the top. Leaves on hirſute petioles of a middling length. Stipules between the petioles, oppoſite, connate, membranaceous, broadiſh at the baſe, with a longer and ſomewhat briſtly point, hirſute, ſhrivelling. Peduncles oppoſite, ſolitary in the axils of the terminating leaves, ſhorter than the leaves, compreſſed, hirſute, at top three-parted, three-flowered. Pedicels forming an umbellet; with four ſmall linear acute leaflets, inſtead of an involucret, at the baſe. Segments of the calyx linear, hirſute, permanent. Corolla larger than the others, duſky-yellow, pubeſcent on the outſide: tube elongated, widening towards the border, which has five roundiſh convex ſegments: aperture crowned with a ring. Filaments as in *thyrſoidea.* Style bifid at the top. Capſule roundiſh, crowned with the ſegments of the calyx, two-celled, two-valved: valves bipartile: partition contrary. Seeds very many, but two ripening in each cell; theſe are angular-convex; the reſt are ſmall, flat and membranaceous.

Native of Jamaica, on rocks near ſtreams; flowering in april.

It is diſtinguiſhed by its ſhagginеſs, the ſize of the flowers, and the inflorеſcence.

Browne's Peteſia, n. 3. ſeems to appertain to this ſpecies, rather than to the preceding.

11. Shrub from two to three feet in height, upright, branched, rugged. Branches round, rigid, rugged. Leaves moſtly terminating, on round tomentoſe-hoary petioles, oppoſite, entire, nerved, netted-veined, ſmooth, ſomewhat ſhining, underneath hirſute, rugged, rigid, ſomewhat leathery. Stipules within the baſe of the petioles, very ſhort, truncate, whitiſh-ciliate at the edge. Flowers ſubumbelled, on very ſhort pedicels, with a two-leaved involucret: leaflets ovate-acute, concave, pubeſcent-hoary. Calyx five-parted: ſegments ovate, acute, thick, rigid, ſilky-hoary within and without: five other little ſegments at the baſe of the germ; and two ovate-acute leaflets at the baſe of the calyx. Corolla biggiſh: tube the length

Digitized by Google

length of the calyx and hoary: border five-parted: ſegments ovate, convex, rigid, hoary: aperture margined. Filaments from the middle of the tube. Anthers below the border. Germ oblong, truncate at the top, hirſute: ſtyle bifid at the top: ſtigmas thicker. Capſule oblong, clothed and crowned with the calyx, two-celled, truncate at the top, perforated in the centre, two-valved, with the valves bipartile: partition contrary. Seeds very many, ſmall, oblong, membranaceous, two only ripening. This ſpecies is very diſtinct in its habit, flowers and hoarineſs.

Native of Jamaica, in the rocky calcareous mountains, but rare.

12. This ſhrub is a fathom high, branched and even. Branches ſubdivided, round-flatted, looſiſh, rugged; twigs hirſute. Leaves on ſhort, hirſute, rufeſcent petioles, decuſſated, in the middle widiſh, acute, entire, nerved and veined, pale underneath. Stipules oppoſite, wide, ovate-lanceolate, long, hirſute. Peduncles oppoſite, ſolitary, nearly the length of the leaves, filiform, three-parted at top, trifid, hirſute. Flowers pedicelled, yellowiſh, hirſute on the outſide. Leaflets minute, oppoſite, linear, acute, hirſute, at the ſubdiviſions of the peduncles. Calyx five-cleft: ſegments lanceolate, acute, upright, hirſute. Corolla ſalver-ſhaped: tube the length of the calycine ſegments, round, narrower towards the border, hirſute on the outſide; border five-cleft, ſpreading; ſegments oblong, blunt, ſhort, incumbent: aperture contracted, ſcarcely margined. Filaments inſerted into the middle of the tube: anthers oblong, within the tube. Germ ovate, hirſute: ſtyle the length of the tube, bifid at the top. Stigmas erect, acute.

Native of Jamaica, on mountains in the ſouthern part; flowering in january [a].

13. This is very nearly related to *R. odorata*; but it differs from it in its axillary inflorescence, and larger ſharper leaves, not rugged above, ſcarcely cordate at the baſe, and longer petioles. The tube of the corolla in this is only double the length of the calyx. Style protended beyond the aperture. Stigmas erect, converging. Corolla yellowiſh or rufeſcent [b].

It agrees in many reſpects with *R. piloſa* or *triflora* of Vahl; which however is diſtinguiſhed from this, by having the leaves generally narrower, tomentoſe-hoary, often cluſtered towards the ends of the branchlets; the peduncles only three-flowered, the flowers four-ſtamened, and many of the ſeeds ripening.

R. hirta differs from *hirſuta* in the leaves being rigid and nerved; the branches and peduncles ſtiff and upright, not looſe:—from *R. umbellulata*, in the leaves not being lanceolate-ovate, acute; the flowers in umbels not cluſtered [c].

Native of Jamaica. Introduced about 1776, by John Blackburne, Eſq. It flowers from june to auguſt [d].

14. Branches ſmooth, jointed: joints two inches long, gradually leſs upwards, the lower roundiſh, the upper flatted a little and ſometimes four-cornered, the upper compreſſed-ancipital, widening at the top: branchlets oppoſite, ſpreading, ſhort. Leaves oppoſite, an inch long, nerved and ſomewhat veined, quite entire, a little bent back at the edge, paler underneath, ſharp at the baſe, ending in an obſcure point, on very ſhort petioles. Peduncles oppoſite, a little longer than the petiole, one-flowered, ſometimes but very ſeldom in the laſt axils three-flowered with a ſmall leaf on each ſide, and in the middle on both ſides a minute hoary bracte. Calycine ſegments four, linear, bluntiſh, permanent; in the fruit reflex. Tube of the corolla hoary, filiform: aperture crowned with a ſhort ring: border four-cleft, with oblong ſhort blunt ſegments. Filaments ſcarcely any: anthers four linear erect ſtretched at the tip a little beyond the tube. Germ ſmall oblong: ſtyle the length of the tube: ſtigma ſubbifid, with one ſegment a little ſhorter than the other. Capſule the ſize of black pepper, globular, hoary, with a groove on each ſide, crowned with the reflex calyx, two-valved, two-celled, two-ſeeded.

Native of Montſerrat. *Ryan.*[e]]

[a] Swartz. [b] Hort. kew. [c] Swartz. [d] Hort. kew. [e] Vahl.

PROPAGATION AND CULTURE.

Theſe plants being very tender, cannot be preſerved in England, unleſs they are kept in a warm ſtove. They are propagated by ſeeds, which ſhould be ſown on a hot-bed early in the ſpring; and when the plants are come up and fit to remove, they muſt be tranſplanted into ſeparate ſmall pots, and plunged into a moderate hot-bed of tanner's-bark, where they muſt be treated in the ſame manner as hath been directed for other tender plants from the Weſt Indies; in winter they muſt be placed in the tan-bed in the ſtove, where theſe plants will thrive, and in two or three years will flower, when they will make an agreeable variety amongſt other tender exotic plants, for they retain their leaves all the year.

Irioh verticillatum. *Burm. prodr.* 6.

DESCRIPTION, *&c.*

This is a ſuffruticoſe plant, with the habit of Droſera. Leaves cluſtered, alternate, ſeſſile, half-embracing, awl-ſhaped, with filiform teeth ciliate. Scape branched into peduncles; which are axillary and terminating, few-flowered in a ſort of ſpike, each pedicel having one bracte. The whole plant, like Droſera, is viſcid with glandular hairs [a]. Capſule pyramidal, acuminate, roundly three-cornered: partitions faſtened to the axis, and ſeparating in ſuch a manner from the valves when ripe, that a three-ſided pyramidal column remains in the midſt. In each cell is one ſeed, biggiſh, ovate, compreſſed a little, flattiſh on the back, obſcurely angular on the belly, deeply honeycombed with very minute excavations in longitudinal rows, of a reddiſh-ferruginous colour. The ſeeds are faſtened to the axis of the capſule, a little above the baſe [b].

Native of the Cape of Good Hope.]

ROSA. (*From the Greek* Ροδον; *changing the* ρ *into* σ: *and that from* οζω, *or* ρεον *and* οδμη.)

Lin. gen. n. 631. *Reich. n.* 687. *Schreb. n.* 863. *Tournef. t.* 408. *Juſſ.* 335. *Gærtn. t.* 73.

Claſſ. 12. 5. Icoſandria Polygynia.

Nat. order of *Senticoſæ*. *Roſaceæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed: *tube* ventricoſe, contracted at the neck; with the *border* ſpreading five-parted, globular: *ſegments* long, lanceolate-narrow (in ſome of them two alternate ones appendicled on both ſides; two others, alſo alternate, naked on both ſides; the fifth appendicled on one ſide only.)

COR. *Petals* five, obcordate, the length of the calyx, inſerted into the neck of the calyx.

[a] Linn. and Juſſ. [b] Gærtner.

Digitized by Google

STAM. *Filaments* very many, capillary, very ſhort, inſerted into the neck of the calyx. *Anthers* three-cornered.

PIST. *Germs* numerous, in the bottom of the calyx. *Styles* as many, villoſe, very ſhort, compreſſed cloſe by the neck of the calyx, inſerted into the ſide of the germ. *Stigmas* blunt.

PER. none. *Berry* fleſhy, turbinate, coloured, ſoft, one-celled, crowned with the rude ſegments, contracted at the neck, formed from the tube of the calyx.

SEEDS numerous, oblong, hiſpid, faſtened to the inner ſide of the calyx.

OBS. *The calyx of the Pericarp reſembles a berry.*

ESSENTIAL CHARACTER.

Cal. pitcher-ſhaped, five-cleft, fleſhy, contracted at the neck. *Petals* five. *Seeds* very many, hiſpid, faſtened to the inner ſide of the calyx.

DESCRIPTIONS, *&c.*

[This genus can ſcarcely be miſtaken; every body knows a Roſe at firſt ſight. It conſiſts of Shrubs, which for the moſt part are prickly. The leaves are unequally pinnate, with wing-ſhaped ſtipules faſtened to the common petiole. The flowers are either ſolitary or in a ſort of corymb at the ends of the branches; in their natural ſtate they have five petals, which are often large and generally red, but ſometimes white, ſeldom yellow. The tube of the calyx becomes a ſort of berry, crowned with the border; and being of a globular ſhape in ſome ſpecies, and ovoid in others, the genus divides commodiouſly into two ſections[g].

But though the genus be eaſy, it is very difficult to determine the ſpecies, or to aſcertain what is a ſpecies and what a variety. Scopoli, Gerard and others, regard all the European ſpecies as varieties from one ſource. Haller, on the contrary, thought he perceived ſufficient marks of diſtinction, accompanied with no more obſcurity than in other large genera. Linneus remarks, that the ſpecies of Roſes are not without great difficulty circumſcribed within any certain limits, and perhaps that there are no ſuch limits ſet by nature.

Much pains has been beſtowed in Aiton's catalogue of the Royal garden at Kew, to aſcertain and characterize moſt of the ſpecies known in Europe, either wild or in gardens, and the ſeveral varieties are there ſet down under each. It is of little conſequence whether all theſe were originally diſtinct or not, if they now maintain their difference, and are generally acknowledged for ſpecies. It is ſcarcely neceſſary to add that the Roſe has been a favourite flower, in all ages, among all the poliſhed people both of Aſia and Europe. Some ſpecies are found in Africa, and others in North America. We are not acquainted with the native country of ſome double Roſes, and they are probably creatures of art and cultivation. The firſt ſpecies is the only one which has ſingle leaves.

1. Stem pubeſcent with ſtout hooked prickles. The leaves are different from all the other ſpecies, being ſimple, ovate, on very ſhort petioles, toothed, glaucous. Peduncles terminating the branchlets, ſhort, one-flowered, pubeſcent, with a few prickles. The tube of the calyx (germ, *Lin.*) is covered with numerous prickles. Petals obovate, yellow with a red ſpot at the baſe.—Native of northern Perſia[h].]

2. The ſingle Yellow Roſe has weak ſtalks, which ſend out many ſlender branches, cloſely armed with ſhort crooked brown prickles. Leaflets two or three pairs, ovate and thin, ſmooth, of a light green, ſharply ſerrate. Flowers on ſhort peduncles, ſingle, bright yellow, without ſcent.

[Leaves obovate, biſerrate, five or ſeven, ſmooth even underneath. Stem beſet, not here and there, but cloſely with ſtraight prickles. Segments of the calyx tomentoſe within, ſeldom pinnatifid. Petals large, obcordate, or two-lobed with a large rounded ſinus[i].

Authors differ as to the ſcent of the flowers. Miller ſays they have none; Parkinſon, that they are without any great ſcent whilſt freſh, but a little more, yet ſmall and weak when dried; Retzius ſays that they ſmell like bugs; and from this circumſtance Allioni names this ſpecies *Roſa fœtida*. The leaves, according to Linneus, ſmell very ſweet; and according to Krocker, they have a pleaſant vinous ſmell. Gerarde ſays, they have an excellent ſweet ſmell, more pleaſant than thoſe of the Eglantine.

Native of Germany, the South of France and Italy. Cultivated by Gerarde in 1596[k].]

β. The Auſtrian Roſe has the ſtalks, branches and leaves like thoſe of the ſingle yellow Roſe, but the leaves are rounder. The flowers are alſo larger; the petals have deep indentures at their points; are of a pale yellow on the outſide, and of a reddiſh copper colour, orange-ſcarlet or Barré colour within; are ſingle; have no ſcent, or a diſagreeable one; and ſoon fall away. It has ſometimes flowers entirely yellow on one branch, and copper-coloured on another.

[g] Juſſieu. [h] Willdenow. [i] Retzius. [k] Hort. kew.

Digitized by Google

[Ray ſays that the flowers ſmell like honey: to me they ſmell more like bugs; but the ſcent varies much.

According to Jacquin the petals are brimſtone-coloured on the outſide, and bright ſcarlet within, the flowers are in ſuch abundance as in a manner to cover the whole ſhrub, and their ſcent is unpleaſant and even rather fetid. Branches ſmooth, with ſtraight prickles, Petioles ſomewhat hirſute. Peduncles and calyxes very ſmooth. Petals obcordate, but ſometimes ſcarcely emarginate.

3. This differs from the preceding, not only in the doubleneſs of the flowers, but in having the leaflets ſimply ſerrate, not glandular, pubeſcent and glaucous underneath; whereas in R. lutea they are doubly ſerrate, glandular and glutinous, and of a ſhining green colour, the ſtipules lacerated; the fruits hemiſpherical and glandular, which in the other are ſubglobular and ſmooth. The prickles on the ſtem are of two ſorts in this; a few being larger, and many ſmaller[m].

The flower, ſays Parkinſon, is ſo thick and double, that very often it breaketh out on one ſide or another, but a few of them abiding whole and fair in our country: being fair blown open, it doth ſcarce give place for largeneſs, thickneſs and doubleneſs, unto the great Provence or Holland Roſe.

Native of the Levant. It was firſt procured to be brought into England by Maſter Nicholas Lete, a worthy merchant of London, and a great lover of flowers, from Conſtantinople; which, as we hear, was firſt brought thither from Syria; but periſhed quickly both with him, and with all other to whom he imparted it: yet afterwards it was ſent to Maſter John de Franqueville, a merchant alſo of London, and a great lover of all rare plants, as well as flowers, from which is ſprung the greateſt ſtore, that is now flouriſhing in this kingdom[n].

Johnſon ſpeaks of it as of a ſhrub ſtill of great rarity, in 1633. Mr. Miller regards it as a variety of the ſingle Yellow Roſe. He ſeldom errs on that ſide. It flowers later than that, namely in july.

4. Hudſon's-bay Roſe has the ſtems, when full grown, unarmed; the younger ones, or thoſe of the firſt year, are armed with ſlender ſtraight prickles bent a little back at the top. Branches round, unarmed, ſhining, reddiſh. Leaflets commonly ſeven, oblong, ſharply and almoſt equally ſerrate, ſmooth. Petioles ſmooth, generally armed with one or two ſpinules.

Native of Newfoundland and Hudſon's-bay. Cultivated in 1773, by Mr. James Gordon. It flowers from may to auguſt[o].]

5. The Cinnamon Roſe riſes about four feet high. The branches are covered with a purpliſh ſmooth bark, and have no ſpines, except at the joints immediately under the leaves, where they are commonly placed by pairs; they are ſhort and crooked. Leaflets ſeven, ovate, ſerrate, hairy on their under ſide. Leaves of the calyx narrow and entire. Flower ſmall, with a ſcent like Cinnamon, whence its name.

[The ſingle Cinnamon Roſe, ſays Parkinſon, hath his ſhoots ſomewhat red, yet not ſo red as the double kind; armed with great thorns, like almoſt unto the Eglantine buſh; thereby ſhowing, as well by the multiplicity of its ſhoots, as the quickneſs and height of his ſhooting, his wild nature. The Roſes are ſingle, ſomewhat large, and of a pale red colour.

Native of the South of Europe.

β. The ſhoots of the Double Cinnamon Roſe are redder; the flowers ſmall, ſhort, thick and double, of a pale red colour at the end of the leaves, (petals) ſomewhat redder and brighter towards the middle[p].]

It is the ſmalleſt and earlieſt of the double garden Roſes; [flowering in may. Hence ſome authors call it *maialis*, but have ſuppoſed it to be different from the Cinnamon Roſe. Retzius thus deſcribes it. The root creeps much. The ſtems are from ſix to eight feet high, half-jointed, prickly; the prickles cloſer towards the bottom; they are ſtraight and recurved; under the joints larger. The branches have only two or three prickles at the baſes of the branchlets and petioles. Petioles without prickles, but rough-haired, widening into ſerrate ſtipules; the ſerratures ſphacelate-glandular. Leaflets five or ſeven, oblong, ſerrate beyond the middle, rough-haired underneath but ſmooth above, veined on both ſides. Peduncles naked, ſmooth, ſolitary or two and three together. Fruits ſubglobular, naked, ſmooth. Segments of the calyx ſmooth, entire, widening at the end, longer than the corolla, rough-haired within and at the edge; ſometimes one of the ſegments has a few linear jags. Flowers ſmall, full, pale red. It agrees with *Roſa fœcundiſſima* of Du Roi (2. 345.), except that Retzius did not obſerve any prickles upon the petioles. It is the *R. maialis* of Hermann (*diſſ. de Roſa, p.* 8. *n.* 3.): *R. collineola* of Ehrhart (2. 70.): and the *cinnamomea* of Miller: but Retzius can ſcarcely think it to be the *cinnamomea* of Linneus[q].

The petioles in our garden Cinnamon Roſe are not rough-haired (hirti) but villoſe, as are the leaflets underneath, giving them a glaucous hue. The ſtipules are of a very pale yelloviſh green, ſometimes tinged with red at the back along the midrib. The common petiole has prickles along it on the young ſhoots only.

Gerarde, who cultivated it in 1596, calls it the Canell or Cinnamon Roſe, and ſays that it took this name, not of the ſmell of its flowers, as ſome have deemed, for they have little or no ſavour, but from the ſmell of the leaves. I cannot diſcover any ſmell of Cinnamon either in the leaves or flowers.

6. White Dog-Roſe has round, glaucous, often mahogany-coloured ſtems; with very long, thong-like branches, bowing, with ſcattered, hooked prickles, ſmaller than in the common Dog-Roſe. Leaflets five or ſeven, but moſtly five, ovate, pointed, ſmooth, ſimply ſerrate, glauceſcent underneath. Petioles prickly. Peduncles three or five in a terminating cyme, (rarely ſolitary) mahogany-coloured, covered with a glandular roughneſs, not all exactly from one point, accompanied by a few lanceolate bractes, and each bearing a ſingle white flower, like the common Dog-Roſe, but never red or bluſh-coloured, and leſs fragrant. Fruit oblong; but in ripening it becomes globoſe, and deep red. The ſtyles, as ſoon as they have paſſed through the neck of the calyx, are compacted into a cylinder, reſembling a ſingle ſtyle, terminated by a knob compoſed of the ſtigmas. This circumſtance alone will diſtinguiſh it from the other ſpecies[r].

Native of England, Switzerland, Germany, Dauphiné, Piedmont, and probably other parts of Europe, where it may not perhaps have been diſtinguiſhed from R. canina. It is however ſufficiently diſtinct. With us it is frequent in hedges, and thickets; flowering in june and july. It is ſaid to be the moſt common wild Roſe in the weſt of Yorkſhire and about Mancheſter. Mr. Robſon has not obſerved it within fifty miles of Darlington.

7. The ſmall Burnet-leaved Roſe has been confounded with the *ſpinoſiſſima*, or what we commonly call the Scotch Roſe; and others think it is not diſtinct from that.

Pallas ſays, that the ſhrub, as it appears in the open graſſy ſteppes of New Servia and New Ruſſia, is quite the ſame with the European. It is three feet high, with ſtouter prickles thinly ſcattered, as in the garden plant. Stipules long, entire. Petioles ſpinuloſe. Leaflets ſeven. Peduncles hiſpid. Segments of the calyx ſeldom pinnate. Corolla white. In the garden plant there are larger and ſetaceous prickles intermixed, and nine leaflets, the lower ones ſmaller. The flowers are white, and the ſegments of the calyx entire.

The Siberian ſhrub is very elegant, a foot and half or at moſt two feet in height; the trunk thorny all over, the thickneſs of the little finger, very much branched, the branches collected into an ovate form. Spines on the trunk and branches very frequent, briſtle-ſhaped, tranſverſe or reclining, gray. Leaves very ſmall, on red petioles, ſometimes ſmooth, ſometimes with ſmall prickles on them. Stipules very narrow

[m] Ehrhart. [n] Park. parad. 420. [o] Hort. kew. [p] Parkinſon. [q] Obſ. 3. 33. n. 60. [r] Smith, brit. Engl. bot. and Stokes in Withering.

with wider earlets, external and ſerrate. Leaflets commonly ſeven, but ſometimes nine or five, the ſize of the little finger nail, oval, cut round, ſharply double-ſerrate, ſtiffiſh, rugged, more or leſs retuſe, on ſome ſhrubs rather acute. Peduncles ſometimes rough, ſometimes ſmooth, with a ternate and ſimple leaf, almoſt to the flower. Fruit globoſe, ſmooth. Segments of the calyx linear-attenuated, tomentoſe at the edge, ſhorter than the petals; which are yellowiſh-white and ſubcordate. Fruit when ripe black, dry, inſipid, crowned with the ſegments of the calyx.

Retzius diſtinguiſhes it by the following marks. Stems not decumbent but upright. Segments of the calyx villoſe on the interior margin; the ends dilated, twice trifid. Flower the ſize of the Dog-Roſe, but white, tinged here and there ſlightly with red. Petioles underneath, and generally alſo the ribs of the leaves, prickly. Serratures of the leaflets glandular at the end. Stipules alſo ſerrate, and the ſerratures glandular.

Native of the South of Europe, as well as Aſia. It flowers here in may and june.

8. The Burnet or Scotch Roſe has its ſtems about two feet high, upright, much branched, with numerous ſtraight, unequal, very ſlender needle-like prickles, on the young branches, which often diſappear from the old ones. Leaflets ſeven or nine, ſmall, roundiſh, blunt, ſerrate, ſmooth, ſeſſile. Their common petiole is ſometimes prickly. Peduncles ſolitary, one-flowered, ſmooth, or very ſeldom prickly. Stipules ſmall, halbert-ſhaped, toothed. Tube of the calyx almoſt hemiſpherical, ſmooth: the ſegments are entire. Petals white or cream-coloured, yellow at the baſe, delicately fragrant, ſometimes ſtriped with red. Fruit globoſe, deep red, black when quite ripe, ſmooth, ſometimes, as Haller deſcribes it, ſomewhat prickly. The prickles on the ſtem and branches are very unequal in ſize; ſome are flat, others like needles [a].

According to Mr. Woodward, the petioles are not prickly; in my own notes the branches and midrib of the leaves are ſaid to be prickly; the leaflets from three to five pairs; the peduncles ſmooth; the fruit ſubglobular, ſmooth and ſhining, of ſo dark a purple when ripe, as to appear black on the outſide. The pericarp is full of a fine purple juice. Dr. Withering informs us, that this diluted with water, dyes ſilk and muſlin of a peach-colour; and with the addition of alum a deep violet: but that it has very little effect on woollen or linen. He adds, that the ripe fruit is eaten by children, and has a grateful ſubacid taſte; that its dwarfiſh growth, and the ſingular elegance of its little leaves, reſembling thoſe of the upland Burnet, entitle it to a place in the flower garden.

Native of moſt parts of Europe; with us on the borders of fields, on heaths and downs, in hedges and on ditch banks, on a gravelly or ſandy ſoil: as near Yarmouth, about Worceſter and Bewdley, Perran downs, Cornwall, by Dudiſton-loch in Scotland, &c.

β. Sibbald mentions a variety growing upon a hill at his Ciphian farm, with variegated flowers, red ſtriped with white.]

γ. This ſeldom riſes more than a foot high. The ſtalks are covered with a brown bark, and are cloſely armed with ſmall ſpines; the leaves are very ſmall; the flowers are alſo ſmall, ſeſſile, and of a livid red colour; the fruit is round, of a deep purple colour inclining to black when ripe.

δ. Dr. Withering ſpeaks of a ſpecimen from Lanſcale Haws in Lancaſhire, with prickly peduncles, and cream-coloured flowers, changing to white. Mr. Atkinſon, who ſent it, relates that it covers ſeveral acres of ſand, to the excluſion of every other vegetable.

It appears from Linneus's herbarium, that his *Roſa pimpinellifolia* is exactly, as Haller believed, the ſame plant as his original *ſpinoſiſſima*, and not even a variety [c].

9. This very much reſembles the two following ſpecies; but differs in having the ſtem two feet high, the petioles hairy at the top, and the flowers in pairs [d].

It riſes with ſeveral ſlender ſtems to the height of two or three feet, covered with a browniſh-green bark, and armed with a few ſharp ſpines. Leaflets ſeven or nine, oblong-ovate and ſharply ſerrate. The leaves of the flower-cup have often linear leafy elongations. The corolla is ſingle and of a pale reddiſh colour. There is a variety of it with a double flower [e]. Mr. Marſhall calls this ſpecies the Dwarf Penſylvanian Roſe. In the Kew catalogue it is not diſtinguiſhed from the Carolina Roſe.

10. Stem four or five feet high, petioles ſmooth, leaves ſhining, flowers in pairs [f].]

It riſes with ſeveral ſmooth ſtalks to the height of five or ſix feet. The young branches are covered with a ſmooth purple bark. The leaves are compoſed of four or five pairs of ſpear-ſhaped leaflets, ſmooth on both ſides, of a lucid green on the upper ſurface, but pale on the under, and deeply ſerrate. Segments of the calyx long, narrow and entire. Flowers of a livid red colour, ſingle, with little ſcent. They appear in july.

[According to Dillenius, the ſtems are ſlender and green, with very few ſpines; the branches alſo are ſlender and ſmooth, or very ſeldom prickly. Leaves ſmooth, like thoſe of the Dog-Roſe, but ſomewhat narrower; leaflets five or ſeven, not ſerrate the whole length, but only from a little above the middle to the end. Flowers on ſhort peduncles, ſolitary, a little ſmaller and of a deeper red than thoſe of the common wild Roſe, and ſmelling ſweet like the Damaſk Roſe. Calyxes cut into oblong pointed ſegments: theſe, with the fruit, and the leaf-ſtalks, have ſlender hairs on them. The fruit is ſmall and round, but does not ripen in England. It is not the *Roſa virginienſis* of Parkinſon, theat. 1017. and Ray, hiſt. 1473.—Nor is it the *virginiana* of Du Roi.—It was cultivated in 1726, by James Sherard, M.D. at Eltham [g].

11. Stem five or ſix feet high, ſmooth. Stipular prickles two. Leaflets ſeven, oblong-ovate or nearly lanceolate, ſmooth, not ſhining but opaque, ſerrate, paler underneath. Petioles prickly. Peduncles ſeveral, branched, forming a corymb, unarmed, with glandular hairs ſcattered over them. Leaflets of the calyx undivided, hiſpid on the outſide. Petals obcordate, red. It flowers late [h].

Theſe three ſpecies are natives of North America.

12. The Apple Roſe grows upright to the height of four feet or more: the branches are upright and ſhort. Prickles on the ſtem and branches ſcattered, ſmall, awl-ſhaped, nearly ſtraight. Leaflets ſeven, elliptical, bluntiſh, clothed on both ſides with ſhort velvet-like down, fragrant when rubbed, their ſerratures fringed with glands. Petioles downy, prickly, glandular. Peduncles terminating, moſtly ſolitary, one-flowered, rough with rigid glandular briſtles. Germ globular, briſtly. Segments of the calyx long, downy, prickly on the outſide. Corolla of a full roſe-colour, not very odoriferous. Fruit globular, larger than in any other ſpecies, for the moſt part briſtly, blood-red [i].

According to Mr. Woodward, the peduncles, tube of the calyx, petioles, edges of the ſtipules, and ſerratures of the leaflets are beſet with hairs of various lengths, terminated by a gland: the leaflets are ovate-lanceolate, more or leſs pointed: the petals longer than the calyx: and the fruit not always hiſpid. Dr. Stokes obſerves, that the leaflets are doubly ſerrate.

Retzius informs us, that a large variety of this, brought from Holland, and planted in a fertile ſoil, produced fruit that was quite ſmooth; and then, being tranſplanted into a worſe ſoil, the fruit became very hiſpid. The experiment however, when repeated, did not ſucceed.

The Apple Roſe, well known in gardens, and plantations, both in a ſingle and double ſtate, is found in many parts of Europe and Aſia. It grows copiouſly with us in Weſtmoreland, Cumberland, and the north of Yorkſhire, as well as in ſome parts of Scotland, as in the way from Edinburgh to Ravelſton wood, about Killin in Breadalbane, upon the coaſt of Fife, &c.

Digitized by Google

It flowers in june, and the large deep-red fruit remains till eaten by birds or deſtroyed by froſt and wet.

β. Dillenius mentions a downy-leaved Roſe, found by Sherard near Kingſton upon Thames, which by his deſcription ſeems to be a variety of this [c].]

The fruit has a pleaſant acid pulp ſurrounding the ſeeds, which is ſometimes made into a conſerve or ſweetmeat, and ſerved up in deſerts.

[13. Branches round, ſubtomentoſe, cloſely covered with ſpreading white prickles, ſome larger and others ſmaller. Leaflets four pairs, ovate, blunt with a point, ſerrate, green and wrinkled on the upper ſurface. Petiole tomentoſe, with ſcattered patulous white prickles. Calyx tomentoſe within, hirſute without. It differs from all the other ſpecies, in having the leaflets blunt with a point, wrinkled and tomentoſe; and the branches exceedingly prickly and hiſpid. Native of Japan [d].]

14. The common Provence Roſe is well known in the Engliſh gardens, and is one of the moſt beautiful ſorts yet known. The flowers are ſometimes very large, and the petals cloſely folded over each other, like Cabbages, whence this variety is called the Cabbage Roſe. The flowers of the Provence Roſe have the moſt fragrant odour of all the ſorts.

[The great double Damaſk Province or Holland Roſe, hath his bark, ſays Parkinſon, of a reddiſh or brown colour. The leaves are likewiſe more reddiſh than in others, and ſomewhat larger. It uſually groweth very like the Damaſk Roſe, and much to the ſame height. The flowers are of the ſame deep bluſh colour, or rather ſomewhat deeper, but much thicker, broader, and more double by three parts almoſt, the outer leaves turning back; when the flower hath ſtood long blown, the middle part itſelf being folded hard with ſmall leaves. The ſcent cometh neareſt unto the Damaſk Roſe, but yet is ſhort of it by much.

β. The ſtem and branches of the Red Provence Roſe are not ſo great as thoſe of the other, but greener, the bark being not ſo red. The flowers are not ſo large, thick and double, but of a little deeper damaſk or bluſh colour, turning to red, but not coming near the full colour of the beſt red Roſe: nor is the ſcent ſo ſweet as that of the damaſk Provence, but coming near that of the ordinary red Roſe. This is not ſo plentiful in bearing as the Damaſk Provence [e].]

γ. The ſtalks of the Bluſh Provence Roſe riſe from three to four feet high, and are unarmed: the leaves are hairy on their under ſide: the peduncles have ſome ſmall ſpines: the ſegments of the calyx are ſemipinnate: the corolla has five or ſix rows of petals, which are large, and ſpread open; they are of a pale bluſh colour, and have a muſky ſcent.

[δ. The White Provence Roſe differs only in the colour of the flowers.

ε, ζ. The two dwarf Provence Roſes, both called Roſe de Meaux, differ from each other in little except ſize. The ſmaller of the two is generally known by nurſerymen and gardeners by the name of Pompone Roſe. This throws out numerous ſtems, which rarely exceed a foot or a foot and half in height; uſually ſtraight, rigid and very prickly. Flowers very ſmall, and diſtinguiſhed by the brilliant colour of the central petals: they appear in june [f].

Theſe laſt are of late introduction, but the others were cultivated by Gerarde in 1596, and probably much earlier. They flower from june to auguſt.]

15. This riſes with prickly ſtalks about three feet high. The leaves have three or five leaflets, which are large, oval, ſmooth, and of a dark green with purple edges. The peduncles are ſet with brown briſtly hairs. The ſegments of the calyx are ſmooth and ſemipinnate. The flowers are very double, and of a deep red colour, but have little ſcent.

[The petals are ſo cloſely wedged together that the flower appears as if it came out of the hand of the turner—*flos quaſi tornatus* [g].

The varieties of this ſpecies are very numerous; the moſt remarkable ones are ſet down from the Kew catalogue. Parkinſon deſcribes the Velvet Roſe; ſaying that the old ſtem is covered with a dark-coloured bark, but that the young ſhoots are of a ſad green, with few or no thorns: the leaves are of a ſadder green than in moſt Roſes, and very often ſeven on a ſtalk: the flower is ſingle; or double with two rows of petals, the outer larger, of a deep red like crimſon velvet; or more double, with ſixteen petals or more in a flower, moſt of them equal. They have all leſs ſcent than the ordinary red Roſe.—Several of the other varieties are of more modern date. The Burgundy Roſe is an elegant little plant, not more than a foot or eighteen inches in height.

According to Loureiro, the *Roſa centifolia* is a native of China.

This ſpecies is confounded with the Damaſk Roſe, and is named *Roſa damaſcena* in the London Pharmacopœia. The petals, which are of a pale red colour, and of a very fragrant odour, are directed for medicinal uſe. The ſmell is extremely agreeable to moſt perſons; but in too great quantities, theſe flowers are ſaid to produce ſneezing, inflammation of the eyes, faintings, hyſterical affections, &c. and where perſons have been confined in a cloſe room with a great heap of Roſes, they have been in danger of immediate extinction of life. From the experiments of Prieſtley and Ingenhouſz this effect ſeems owing to the mephitic air, which theſe and moſt other odoriferous flowers exhale.—Six pounds of freſh Roſes impregnate, by diſtillation, a gallon of water ſtrongly with their fine flavour. On diſtilling large quantities, there ſeparates from the watery fluid a ſmall portion of a fragrant butyraceous oil, which liquifies by heat and appears yellow, but concretes in the cold into a white maſs: an hundred pounds of the flowers, according to the experiments of Tachenius and Hoffman afforded ſcarcely half an ounce of oil.

The ſmell of this oil exactly reſembles that of the Roſes, and is therefore much uſed as a perfume. It poſſeſſes very little pungency, and has been highly recommended for its cordial and analeptic qualities.—The proceſs for making Attar or eſſential oil of Roſes is as follows: Forty pounds of Roſes, with their calyxes, are put into a ſtill, with ſixty pounds of water. The maſs being well mixed, a gentle fire is put under the ſtill; and when fumes begin to riſe, the cap and pipe are properly fixed and luted. When the impregnated water begins to come over, the fire is leſſened by gentle degrees, and the diſtillation continued until thirty pounds of water are come over, which is generally in four or five hours. This water is to be poured upon forty pounds of freſh Roſes, and from fifteen to twenty pounds of liquor are to be drawn from it, as before. It is then poured into pans of earthen ware or tinned metal, and left expoſed to the freſh air for the night. The Attar or eſſence will be found in the morning, congealed and ſwimming on the ſurface of the water.

Theſe flowers alſo contain a bitteriſh ſubſtance, which is extracted by water along with the odorous principle, and remains entire in the decoction, after the latter has been ſeparated by diſtillation or evaporation. This fixed ſapid matter of the petals manifeſts a purgative quality, and it is on this account that the flowers are received in the Materia Medica.

The Pharmacopœias direct a ſyrup to be prepared of this Roſe, which in doſes of a ſpoonful is found to be pleaſant and uſeful as a laxative for children, or to obviate coſtiveneſs in adults. The ſimple diſtilled Roſe-water ſeems to have nothing but its fragrance to recommend it [h].

It was cultivated by Gerarde in 1596 [i].]

16. The ſtalks of this grow erect, and have ſcarce any ſpines; they riſe from three to four feet high. The leaves are compoſed of three or five large oval leaflets, which are hairy on their under ſide. The leaves of the calyx are undivided. The flowers are large, but not very double, ſpread open wide, and

[c] Smith. [d] Thunberg. [e] Parkinſon. [f] Curtis. [g] Linn. ſyſt. [h] Woodville. [i] Hort. kew.

decay

decay ſoon; they are of a deep red colour, and have an agreeable ſcent.

[Stem ſmooth or but little prickly. Peduncles hiſpid. Leaves ſubacute, naked above, ſcarcely tomentoſe or downy underneath. Fruit hiſpid at the baſe. Flowers red or white [k].

This ſpecies does not riſe ſo high as the *centifolia*, but much reſembles it in its foliage. Linneus reſts their ſpecific difference on the greater roughneſs and prickleneſs of the leaf-ſtalks in this, but this circumſtance is not ſufficiently remarkable to found the diſtinction. The petals, though large and ſpreading, are never half ſo numerous as in the *centifolia*, and are of a deep crimſon colour [l].

Parkinſon gives the Red Roſe the epithet of Engliſh, becauſe this and the White are the moſt ancient and known Roſes to our country, and aſſumed by our precedent Kings of all others, to be cognizances of their dignity, and becauſe the Red is more frequent and uſed in England than in other places. The flowers vary in colour; ſome are of an orient red or deep crimſon colour, and very double, although never ſo double as the White; ſome again are paler, tending ſomewhat to a damaſk: and ſome are of ſo pale a red, as that they are rather the colour of the canker Roſe; yet all for the moſt part with larger leaves than the Damaſk, and with many more yellow threads (ſtamens) in the middle. The ſcent hereof is much better than in the White, but not comparable to the excellency of the Damaſk Roſe; yet this being well dried and kept, will hold both colour and ſcent longer than the Damaſk.

β. Neither Gerarde nor Parkinſon mention the *Mundi Roſe*, which has the flowers very elegantly ſtriped or variegated with red and white; in other circumſtances it ſo perfectly reſembles the red Roſe, that there can be no doubt of its being a variety of that; indeed it frequently happens that a red Roſe or two appears on the ſame plant with the variegated flowers [m].]

γ, δ. The Childing, Marbled, and double Virgin Roſes, ſays Mr. Miller, have great affinity with each other.

[The flowers of the Red officinal Roſe poſſeſs neither the fragrance nor the laxative quality of thoſe of the *centifolia*, but are chiefly valued for their aſtringency, which is moſt conſiderable before the petals expand, and therefore in this ſtate they are choſen for medicinal uſe, and ordered in different preparations, as thoſe of a conſerve, a honey, an infuſion, and a ſyrup. Theſe preparations, eſpecially the firſt and ſecond, have been highly eſteemed in phthiſical caſes, particularly by the Arabian phyſicians. Riverius alſo cites ſeveral caſes in point, and that of Kruger, related in the German ephemerides, has been thought a ſtill more evident proof of the efficacy of conſerve of Roſes in phthiſis pulmonalis; but as the uſe of the conſerve was conſtantly joined with that of milk and farinacea, together with proper exerciſe in the open air, it has been doubted if theſe recoveries could be wholly imputed to the Roſes, though their mild aſtringent and corroborant virtues certainly contributed much. In ſome caſes, twenty or thirty pounds of the conſerve were taken in the ſpace of a month.

The infuſion of Roſes is a grateful cooling ſubaſtringent, and uſeful in ſpitting of blood; its efficacy however depends chiefly on the acid. The ſyrup derives its uſe merely from its colour.

Notwithſtanding the reputed aſtringent quality of red Roſes, Poterius relates, that he found a dram of the leaves dried and powdered, occaſioned three or four ſtools, and this not in a few inſtances, but conſtantly in ſeveral. The full blown flowers are ſlightly laxative, eſpecially in the paler ſorts; but the buds of this Roſe are aſtringent.

Both the aſtringency and colour of the petals are beſt preſerved by haſty drying [n].

Gerarde ſays, in Leylande fields in Lancaſhire, our garden Roſe doth grow wild, in the plowed fields among the corn in ſuch abundance, that there may be gathered daily, during the time, many buſhels of Roſes, equal with the beſt garden Roſe in each reſpect: the thing that giveth great cauſe of wonder is, that in a field in the place aforeſaid, called Glover's-field, every year that it is plowed for corn, it will be ſpread over with Roſes; but when it is leye, and not plowed, then ſhall there be but few Roſes to be gathered: by the relation of a curious gentleman there dwelling, ſo often remembered in our hiſtory.

I give this improbable tale, as an inſtance of the dependance that is to be placed on the information of curious gentlemen. Johnſon, the emaculator of Gerarde, has ſet it right, by informing us, he had heard that the Roſes which grow in ſuch plenty in Glover's field are no other than the corn Roſe or red Poppies.]

17. The Damaſk Roſe riſes with prickly ſtalks eight or ten feet high, covered with a greeniſh bark, and armed with ſhort prickles. The leaves are compoſed of five or ſeven oval leaflets, dark green above, but pale underneath; the borders frequently turn brown and are ſlightly ſerrate; the peduncles are ſet with prickly hairs; the calyxes are ſemipinnate and hairy; the corolla is of a ſoft pale red, and not very double, but has an agreeable odour; the heps are long and ſmooth.

[Retzius ſays that the ſtipules are quite entire, with a glandular margin; and that the fruits are hiſpid-hairy half over.

It is a native of the South of France, and was cultivated in 1596 by Gerarde [o].

Theſe garden Roſes were certainly cultivated and highly eſteemed in England long before the time of Gerarde, as appears both from our hiſtorians and poets. Though ſome of them are ſet down as indigenous of the South of Europe, yet I cannot help thinking, that they were firſt produced and nurtured in the more benign and earlier cultivated regions of Aſia. Hakluyt ſays that the Damaſk Roſe was brought in by Dr. Linaker, phyſician to King Henry VII. and VIII.

Of this elegant ſpecies, which has not been well diſtinguiſhed from the *provincialis* and *centifolia*, there are many varieties.]

The Monthly, the ſtriped Monthly, the York and Lancaſter, and Mr. Hart's Roſe, ſays Mr. Miller, are all ſuppoſed to be varieties of the Damaſk Roſe.

[α, β. The Red and Bluſh Damaſk Roſe differ only in the ſhade of colour.]

γ. The York and Lancaſter Roſe, agrees with the Damaſk in ſtalk, leaf, &c. differing only in the flower being variegated with white ſtripes. Mr. Hart's Roſe has the white ſtripes more diſtinct. The flowers in theſe being leſs double than in ſeveral others, are frequently ſucceeded by fruit, and have ripe ſeeds, from which other varieties may be obtained [p]. [Some of theſe are particularized by Parkinſon. Sometimes one half of the petal is of a pale whitiſh colour, and the other half of a paler damaſk than common: or one petal is white or ſtriped with white, and the other half bluſh or ſtriped with bluſh; ſometimes alſo all ſtriped or ſpotted over, and at other times little or no ſtripes or marks, as nature liſteth to play with varieties, in this, as in other flowers: the longer it abideth blown open in the ſun, the paler and the fewer ſtripes, marks or ſpots will be ſeen in it. The ſmell is of a weak Damaſk Roſe ſcent.

δ, ε. The Red and White Monthly Roſes are ſo called, from their continuing to blow in ſucceſſion during the greater part of the ſummer; not that they blow in every month, as the name implies. They are in every reſpect like the Damaſk Roſe; unleſs it be, as Ferrarius obſerves, more full of prickles than that [q].]

ζ. The Bluſh Belgick Roſe, which Mr. Miller gives as a diſtinct ſpecies, riſes about three feet high, with prickly ſtalks. The leaves are compoſed of five or ſeven leaflets, which are oval, hairy on their under ſide, and ſlightly ſerrate: the peduncles and calyxes are hairy, and without prickles; the calyxes are large and ſemipinnate; the flowers very double, of a pale fleſh colour, with little ſcent, generally in great quan-

[k] Linn. mant. [l] Woodville. [m] Ray. [n] Woodville. [o] Hort. kew. [p] Mill. fig. [q] Ray.

Digitized by Google

tities. The Red Belgick Roſe differs only in having the colour of the flower a deep red.

18. The Evergreen Roſe has ſlender ſtalks which trail upon the ground unleſs they are ſupported, and if trained up to a pole or the ſtem of a tree, will riſe twelve or fourteen feet high; they are armed with crooked reddiſh ſpines, and have ſmall leaves, with ſeven oval acute leaflets, of a lucid green, and ſerrate. The leaves continue on all the year. The flowers are ſmall, ſingle, white, and have a muſky odour. In their natural place of growth they continue in ſucceſſion great part of the year, but their time of flowering in England is june.

[Parkinſon remarks, that this Roſe-buſh is very like the wild ſingle Eglantine; and that the loweſt pair of leaflets are ſmalleſt, the next bigger, the third bigger ſtill, and the end-leaf biggeſt of all. At firſt coming out, the ſhoots and young leaves are reddiſh; but this, I believe, is common to moſt, if not all the ſpecies. The flowers ſtand four or five together at the tops of the branches; they are of a pure white, much larger than the ordinary Muſk Roſe, and of a fine ſcent.

Native of Germany. Sherard gathered the ſeeds in Italy, and introduced this plant into his garden at Eltham about the year 1727. Mr. Miller relates that in the ſame year he ſaw it growing at Leyden, in the curious garden belonging to Boerhaave; who had it from Micheli; and that the latter found it growing naturally in the woods near Florence. According to Cluſius, Joachim Camerarius ſent the ſeeds to him at Padua, in the year 1592; and as he carried them to Leyden, Boerhaave's plants probably deſcended from them.—Parkinſon cultivated the Evergreen Roſe in 1629[t].

19. The branches have great abundance of prickles, which fall off on the ſtems. The fruits are large and pear-ſhaped.

Native of Auſtria and Italy.

According to the catalogue of the royal garden at Kew, it was introduced about 1773, by Meſſrs. Kennedy and Lee.

20. The young ſhoots of the Frankfort Roſe are covered with a pale purpliſh bark, ſet with a number of ſmall prickles like hairs; the older branches have but few thorns. The fruit is very large. The flower is thick and double as a Red Roſe, but ſo ſtrong ſwelling in the bud, that many of them break before they can be full blown; and then they are of a pale red-roſe colour, between a red and a damaſk, with a very thick broad hard umbone of ſhort yellow threads in the middle. The ſegments of the calyx are quite entire. The ſmell is neareſt unto a Red Roſe[t].]

Mr. Miller ſays, this may be a diſtinct ſpecies, but is of little value; the flowers rarely opening fair, and having no odour.

[Its native place is not known. Parkinſon cultivated it in 1629[t].

21. The Sweet Briar or Eglantine has yellow hooked prickles on the ſtem. Leaflets ſeven, very fragrant, elliptic or ſubovate, above ſmooth and wrinkled, underneath ruſt-coloured with reſinous atoms or little dots; ſerratures glandular. Petioles alſo glandular and prickly. Peduncles muricate and in corymbs. Calyx glandular. Petals roſe-coloured, white at the baſe. Fruit ſcarlet, muricate but ſometimes ſmooth, farinaceous, inſipid[x].

Leaflets doubly ſerrate, ſmooth above except a few ſcattered hairs along the midrib, even in the newly expanded leaves, half-doubled together, not ſo full-ſcented as thoſe of the Garden Sweet-Briar. The habit however and mode of growth of the wild plant are the ſame with that[y]. Dr. Stokes thinks they are at leaſt varieties; the leaves in the garden Sweet-Briar being beſet above with very ſhort hairs, between oval and ovate, and not unfrequently quite oval; the glands yellowiſh; the fruit ſcarlet and ſometimes quite ſmooth; whereas, according to Lightfoot, the fruit of the wild is black, when ripe. Dr. Withering remarks, that the prickles are not numerous on the tube of the calyx, or germ, as Linneus calls it, and chiefly on one ſide; that the ruſty appearance is chiefly confined to the lower leaves; and that the ſweet ſcent ſeems to be owing to the glands.

The garden ſhrub certainly grows larger and more erect, the leaves are bigger and much ſweeter than in the wild one, the ruſty colour of them diſappears, and the whole puts on a more vigorous appearance. But all this is owing to culture, which has done much in this favourite genus.

Native of moſt parts of Europe on heaths, in thickets, hedges and woods, chiefly in a gravelly ſoil.

The varieties with double flowers are very elegant ſhrubs in ornamental plantations.]

22. The Moſs Provence Roſe, commonly called the Moſs Roſe, from the moſs-like pubeſcence on the calyx, has the ſtalks and branches cloſely armed with brown ſpines. The peduncles and calyx are covered with long hair-like Moſs. The flowers are of an elegant crimſon colour, and have a moſt agreeable odour.

[This elegant Roſe is known to us only in its double ſtate, and we are ignorant of the country to which we are indebted for it. By Furber's catalogue it appears that it was cultivated here in 1724[*].

Retzius deſcribes the ſtem as very prickly, and at the ſame time hiſpid; the peduncles long, beſet with curled ſtrigæ terminated by a reſinous globule, as are alſo the whole calyxes; theſe ſtrigæ are often branched. The petioles are leſs hiſpid and unarmed. The leaflets are very large, three or five, ſmooth. The colour and ſmell of the clammy reſinous glands are very much the ſame as in the Flowering Raſpberry, or Rubus odoratus.]

23. The Muſk Roſe riſes with weak ſtalks to the height of ten or twelve feet, covered with a ſmooth greeniſh bark, and armed with ſhort ſtrong ſpines. Leaflets ſeven, light green and ſerrate. Flowers in large bunches, in form of umbels, at the end of the branches, they are white, and have a fine muſky odour, appear in july and auguſt, and continue in ſucceſſion till the froſt ſtops them. The ſtalks are too weak to ſupport themſelves. It varies with double flowers.

[Prickles remote, ſtout, bent back. Leaflets five, ovate, ſerrate, acute, ſmooth. Petioles often prickly, pubeſcent. Flowers numerous, in corymbs. Peduncles hirſute. Calyx oblong, villoſe; the ſegments lanceolate, entire, pubeſcent within. Petals white, obovate, of the ſame ſize with thoſe of the Dog Roſe. It grows every where in hedges in the kingdom of Tunis; and the Tuniſians cultivate it for the ſake of a highly odorous eſſential oil which they obtain from the petals by diſtillation[a].

It was cultivated in 1596, by Gerarde[b]. According to Hakluyt (1582) the Muſk Roſe plant was procured of later time out of Italy.

R. ſempervirens or Evergreen Muſk Roſe of Miller (n. 9.) ſeems to be the ſame with this.]

The ſeeds were ſent by Robert More, Eſq. who found it growing naturally in Spain.

'Stems four or five feet high, erect, covered with a green bark, and armed with ſtrong crooked white ſpines. Leaves compoſed of five oval leaflets ending in acute points, ſmooth, of a lucid green, ſlightly ſerrate, and continuing all the year. The flowers grow in large bunches at the end of the branches; are ſingle, white, and have a muſky odour. They appear in auguſt, and continue in ſucceſſion till october.

[24. The veins of the leaves underneath are red. The ſtem, peduncles and fruits are covered with a glaucous bloom.

Native of the mountains of Dauphiné, Switzerland and Salzburgh.

25. Allied to the following ſpecies, but diſtinguiſhed by the obovate fruit and other marks. Different from *R. pumila* by the leaves not being glaucous underneath, the ſtem and petioles unarmed.—Native of the mountains of Dauphiné and Switzerland[c].

[t] Hort. kew. [t] Parkinſon. [t] Hort. kew. [x] Smith. [y] Withering.

26. The Alpine Roſe is a low ſhrub, with reddiſh-brown ſtems, the lower half or thereabouts of which is covered with ſtraight awl-ſhaped ſlender white not pungent prickles; the upper part is quite naked. Stipules ciliate-glandular at the edge. Petioles hiſpid-glandular. Leaflets commonly ſeven, ſmooth on both ſides, ovate, biſerrate, ciliate-glandular. Peduncles naked, unarmed. Calyx rufous-brown on the outſide; the tube ovate-oblong, naked; the leaflets or ſegments quite entire, ſpatulate, villoſe-white about the edge, villoſe within. Flowers ſolitary, red, middle-ſized.

Gouan has confounded Haller's Roſe, n. 1107. with Linnæus's *pimpinellifolia*. Haller has united the *pimpinellifolia* and *ſpinoſiſſima*, which Du Roi has very well diſtinguiſhed [d].

Jacquin deſcribes the ſtems as from one to four feet in height, branched and upright. Stipules lanceolate, acute, ſerrulate. Leaflets commonly ſeven, but ſometimes five or nine. The peduncles have always hairs, with glandular heads, ſcattered over them. The flowers have a very powerful and ſweet odour. The fruits are generally quite ſmooth, ſometimes but more ſeldom hiſpid. Leaflets of the calyx entire, lanceolate, concave, running out into a very long point. Petals emarginate, of a very deep purple-red colour, but ſometimes paler. Fruit oblong-ovate, contracted into a neck below the calyx, ſometimes a little curved in, ſhining very much, of an elegant red colour, crowned with the converging calyx, and very ſmooth; it always hangs down, and thus approaches very much to *R. pendulina*, from which it differs in little elſe than in never having the peduncles ſmooth, not even in cultivation. It varies in the hirſuteneſs of the ſtems, but they are commonly ſmooth, and the branches are always ſo. The midribs of the leaves and the ſtipules ſeldom have hairs on them. This ſhrub never has any genuine prickles on it.

Native of the Alps, Germany, Auſtria, Piedmont, and Siberia.—Cultivated in 1683, by Mr. James Sutherland. It flowers in june and july [e].]

According to Mr. Miller it riſes to the height of ſix or ſeven feet. The ſtalks and branches have no ſpines, but are covered with a ſmooth reddiſh bark. Leaflets ſeven, thin, oval, ſmooth, bright green, very ſlightly ſerrate, far aſunder. Peduncles armed with briſtly hairs. Leaflets of the calyx long, ſlender in the middle, terminating in an oval leafy point. Flowers ſingle, bright, appearing at the beginning of may; and ſucceeded by long ſmooth ſpear-ſhaped heps. The plants produce a ſecond crop of flowers about the end of auguſt; but theſe fall off, and are not ſucceeded by heps.

[27. Height from a foot to two feet. The ſtem covered with a ſmooth bark, often coloured. Branches weak, alſo coloured, alternate, one-flowered only. Leaves on each branch three or four, compoſed of five or ſeven leaflets, ovate or wedge-truncate, ſmooth, doubly ſerrate; the uppermoſt or outmoſt larger than the others. Stipules running much down, diverging at the end, ſmooth above, rugged underneath with clammy glandular prominent dots, ciliate: becoming bald when far advanced. Peduncle of the ſame colour with the flower, hiſpid, ſhorter than the oppoſite leaf: at the baſe of it is an ovate-lanceolate, ſmooth, ciliate bracte, twice the ſize of the ſtipules. Calyxes ovate; germs hiſpid with prickles; calycine leaflets long, widened at the end, lanceolate, ſerrate, unequal; one or two of them commonly awl-ſhaped and not dilated, having a denſe white cotton along the edge. Petals deep red, two-lobed or emarginate.—It differs from the *alpina* in having ſeven ovate leaves, larger ſtipules more decurrent, rugged underneath, larger bractes, the peduncles more hiſpid and prickly, and the germ rough with ſpinules, and laſtly the calycine leaflets not ſubulate-ſetaceous, but dilated lanceolate [f].

Native of the Pyrenees, the Swiſs Alps, and the mountains of Sileſia.

28. Height from eighteen inches to two feet, ſlender, ſtraight, brown, covered with numerous ſlender innoxious ſpines, bending downwards. The branches have no ſpines, but ſmooth leaves, glaucous green above, and glaucous white underneath, compoſed of five or ſix pairs of leaflets; the midrib is thinly hairy. Peduncles ſhort. Flowers large; petals emarginate, pale fleſh-colour. Fruits long, pendulous, ſmooth, of a fine coral red. Calyxes then ſet with ſlender hairs; but in flowering-time fringed with a hoary lanugo; in other parts ſmooth and without prickles. It flowers earlier than the other Roſes, namely in may; and the fruit ripens in auguſt [g].

Native of North America. Cultivated at Eltham by James Sherard, M.D. in 1726 [h]. Dillenius ſays that the ſeeds were ſent from New England.

29. Petiole prickly, and thinly ſet with glanduliferous hairs, eſpecially towards the baſe. Leaflets orbicular-obovate, ſmooth, concolour, doubly ſerrate, the ſerratures glandular. Stem ſmooth, with prickles commonly in pairs and rencinate below the origin of the leaves. Petals obcordate, white.

Native of the mountains of Dauphiné and Switzerland [i].

30. Stem upright. Branches round, purple, ſmooth, upright. Prickles ſcattered, recurved. Leaves alternate, petioled. Leaflets oppoſite, ſometimes but ſeldom alternate, ſeſſile, ovate, ſerrate, green and pale above, pale and villoſe underneath. Petioles villoſe, with ſcattered ſmall recurved prickles. Flowers terminating in panicles, the ſize of Bramble flowers. Panicle decompound, ſpreading. Peduncles and pedicels villoſe, unarmed. Calyx very hirſute with a white pile, eſpecially at the edge. Corolla white. Germ villoſe, unarmed. It differs quite from the other Roſes in having ſmall flowers in panicles, on villoſe peduncles.

Native of Japan [k].

31. The common Dog Roſe or wild Briar has the ſtem ſmooth, with two alternate hooked prickles between the knots, growing to the height of ſix feet or more. Branches elongated, from upright ſpreading. Prickles conical-hooked, compreſſed, bright red when young, but afterwards aſh-coloured. Leaves alternate, having for the moſt part ſeven ſcentleſs ſerrate leaflets, the ſerratures terminated by minute purple glands; naked and quite ſmooth on both ſides, the upper ſide ſhining, the lower paler; the lower leaflets gradually ſmaller; the midrib and petiole prickly underneath, the edges beſet with purple glands. Stipules finely toothed, the teeth tipped with red, and terminated by a globule. Peduncles forming a ſort of corymb of two or three to ſix flowers together; but ſometimes they are ſolitary, round, even and naked. Calyx pubeſcent within and at the edge; the leaflets lanceolate and long-tailed, two ſimple, two pinnate on each ſide, and one pinnate only on one ſide. Petals obcordate, a little remote, pale red, fainter towards the baſe, ſometimes white, ſweet-ſcented [l]. Fruit, which is a ſort of berry formed from the ripened calyx, ſcarlet, quite ſmooth and ſhining, ſometimes cloſed and ſometimes pervious at the top; containing about thirty ſeeds, which are bony, ovate-acuminate, angular, having white ſilky briſtles diſperſed among them, terminated by the permanent ſtyle, pale: the outer ones are immerſed in the excavations of the fleſhy ſubſtance of the calyx, but thoſe in the middle have fleſhy, ſaffron-coloured, ſubvilloſe peduncles [m]. It is ſometimes ſeen with a hiſpid fruit [n].

Native of Europe, in hedges and woods, decorating them with its lively odorous flowers in the months of june and july. From theſe a perfumed water may be diſtilled, which is ſaid to be much more fragrant than that from garden Roſes. The leaves are recommended as a ſubſtitute for tea, giving out a fine colour, a ſub-aſtringent taſte, and a grateful ſmell, when dried, and infuſed in boiling water. The fruit, commonly known by the name of *Heps*, is agreeable enough when ripe and mellowed by the froſt: beaten up with ſugar, it makes a pleaſant conſerve, more uſed as a vehicle for other medicines, than for any virtue of its own. Care

ſhould be taken in making this conſerve, to remove all the chaffy or prickly fibres or briſtles with the ſeeds, which will otherwiſe produce conſiderable irritation on the primæ viæ. A moſſy protuberance is common on various parts of the wild Roſe, which is occaſioned by an inſect called Cynips Roſæ: formerly, under the name of *Bedeguar* it was uſed medicinally, but it is now juſtly diſcarded. The fruit in winter is much ſought after by birds, eſpecially the pheaſant. Its ſtrong thorns make it valuable for ſtrengthening hedges [o].

32. The downy-leaved Dog Roſe agrees in habit with the common Dog Roſe, except that the leaves are pubeſcent all over, and have a ſubcinereous appearance. It is leſs in all its parts than the Apple Roſe (R. villoſa.) Branches from upright ſpreading, ſubflexuoſe. Prickles on the ſtem hooked, widened at the baſe. Leaflets five or ſeven, ſweet, elliptic-ovate, very ſoftly tomentoſe on both ſides, with the ſerratures glandulouſly ciliate. Petioles tomentoſe, muricate. Peduncles terminating, ſubſolitary, muricate with rigid glandular briſtles. Germ alſo muricate, elliptic. Calyx glandular-hiſpid. Petals whitiſh at the baſe, but the reſt of a beautiful roſe-colour. Fruit ovate, ſcarlet, muricate, nearly of the ſame ſize and ſhape as in the *canina*.

Not uncommon in hedges and thickets. Obſerved about London by Hudſon. At St. Faith's, Catton, and other places near Norwich. In Shropſhire and Wales common. It flowers in june and july [p].

33. This alſo has very much the habit of *R. canina*. Stems round and ſmooth, armed with recurved, ſtrong, pungent, ſhining, browniſh prickles, which are reddiſh when young. Leaflets five, (ſeldom ſeven) ovate or rather roundiſh, acute, ſharply ſerrate, on very ſhort petioles, very dark green and ſmooth above, ſomewhat hoary or villoſe underneath, eſpecially along the nerves and veins and at the edges; the tips of the ſerratures are cartilaginous, and red ending in a brown colour, when examined by a magnifier. The midribs have prickles, ſhort whitiſh hairs, and thinly ſcattered pedicelled duſky red glands. Stipules ſharp and ciliate at the edge; in other parts ſmooth. The leaves differ from thoſe of the *canina*, not only in their pubeſcence, but in being thicker and leſs ſhining. Peduncles round, hiſpid with glands on long pedicels. Germ very ſmooth, or ſometimes with a few of theſe glands towards the baſe. Leaflets of the calyx villoſe within and at the edges, but glandular only at the back and on the leafy edges of the ſegments; two or three of them are pinnate-laciniate, the others quite entire. Petals obcordate, ſweet, fleſh-coloured or paler. Fruit ſmooth and ſhining, red with an orange-coloured pulp, hardly to be diſtinguiſhed from the fruit of the common Roſe.—Native of Auſtria, on hills [q].

34. This is a very dwarf ſhrub, with ſmall flowers. Leaflets five ſmall ovate acute.—Native of Europe [r].

35. Height ſeldom exceeding three feet. Flowers large in proportion to the plant, ſemidouble, with great richneſs of colour (dark red) uniting a moſt delightful fragrance, coming out in ſucceſſion during the greater part of the year, only more ſparingly in the winter months [s]. Segments of the calyx leafy at the end, one larger than the reſt. Germs and peduncles ſometimes but rarely ſmooth [t].

Native of China. Introduced by Gilbert Slater, Eſq. of Knots-green near Laytonſtone [u].

36. This is very nearly allied to the preceding, and perhaps may be only a variety of it [x]. It is diſtinguiſhed from the next ſpecies chiefly by the ſhining ſmoothneſs of the leaflets, and the ciliate hairineſs of the calycine ſegments. The upper leaves are ternate, the lower ones have a ſingle leaflet added, on one ſide, and thus become in ſome degree pinnate [y].—Native of China.

37. Branches unarmed; or ſometimes, but ſeldom, having one or two very ſlender prickles towards the leaves or on the petioles. Leaflets five, tomentoſe underneath, ſmooth above, ſerrate, the outmoſt twice as large as the reſt. Peduncles long, naked, ſimple. Calyx gaſhed, even. Fruit the ſize of that of Sorbus aucuparia.—Native of China [z], and Cochinchina.

38. Stem ſmooth without prickles, ſeeming to be entirely unarmed, with a large ſtem, and branches a foot long. Leaflets five, ſmooth on both ſides, ſimply and remotely ſerrate, the lateral ones an inch and half, the end one two inches long. The petiole has glandular hairs ſcattered over it, and has one or two hooked prickles. Flowers the ſize of thoſe of the Dog Roſe, in a ſort of corymb. Peduncles hiſpid with hairs which are glandular at the tip. Germ oblong, ſmooth. Leaflets of the calyx leafy at the tip, acuminate, toothed, ſmoothiſh on the outſide, tomentoſe within. It ſeems to differ from the preceding.—Native of the Eaſt Indies [a].

39. Stem villoſe, with ſcattered ſtraight prickles. Leaflets five or ſeven, roundiſh-elliptic, ſubcoriaceous, blunt, the upper ſurface ſhining. Flowers fragrant, terminating, ſolitary. Peduncle very ſhort, with lanceolate ſilky-villoſe bractes covering the germ. Leaflets of the calyx undivided, ovate-lanceolate, acuminate, ſilky-villoſe. Petals yelloviſh white obcordate. Native of China [b].

40. The white Roſe, in its wild ſtate, has an affinity to the *arvenſis* (n. 6.); but differs from it in having wider ovate leaves, ſmooth and deep green above, paler and ſlightly hairy underneath, unequally ſerrate and blunt: ſtem and petioles villoſe, prickly: peduncles ſolitary, long, hiſpid: fruits ovate, ſmooth, but more frequently having a few ſlender prickles on them: calyxes ſmooth, green, half-pinnate [c].

Loureiro deſcribes the ſtem as long, ſcandent, branched, having many recurved prickles ſcattered over it. Leaflets three or five, broad-lanceolate, ciliate, on prickly petioles. Flowers pale, without ſcent, many together. Fruits oblong-ovate, ſmooth, on hiſpid peduncles.

Retzius remarks, that the germs and calyxes are ſometimes hiſpid: and D'Aſſo that the ſegments of the calyx are entire.

Parkinſon deſcribes two varieties of the White garden Roſe; one attaining ſometimes the height of eight or ten feet, with a ſtock of a great bigneſs: the other ſeldom higher than a Damaſk Roſe. Both have ſomewhat ſmaller and whiter-green leaves than in many other Roſes, five moſt uſually on a ſtalk, and paler underneath; as alſo a whiter-green bark, armed with ſhort prickles. The flowers in the one are whitiſh with an eye of bluſh, eſpecially towards the bottom, very double, and for the moſt part not opening ſo fully as the Red or Damaſk Roſe. In the other more white, leſs double and opening more. Some have only two or three rows of petals; and all have little or no ſmell. Native of Europe, China, Cochinchina, &c.

All theſe ſorts of Roſes ſays Gerarde in 1597, we have in our London gardens; that is the White, Red, Province or Damaſk, leſſer Damaſk, and greater Province: and doubtleſs they were in our gardens long before his time. He affirms that the Double White Roſe grew wild in many hedges of Lancaſhire in great abundance, even as Briers do with us in the ſoutherly parts. But Gerarde muſt have been miſinformed, perhaps by the ſame perſon who ſent him intelligence of Red Roſes, which proved to be Corn Roſes or Red Poppies.]

PROPAGATION AND CULTURE.

Moſt of the ſorts of Roſes are of foreign growth, and have been at various times introduced into the Engliſh gardens, but they are generally natives of northern countries, or grow upon the cold mountains in the warmer parts of Europe, ſo they are very hardy in reſpect to cold, but love an open free air, eſpecially the Yellow Roſe, the Auſtrian Roſe, and the Monthly Roſe. The two former will not flower in a warm ſoil and ſituation, nor near the ſmoke of London, and the Monthly Roſe will flower much better in a free

[o] Curtis, Withering, Woodville. [p] Smith. [q] Jacquin. [r] Willdenow. [s] Curtis. [t] Willdenow. [u] Curtis. [x] Willdenow. [y] Jacquin. [z] Willdenow. [a] Linn. ſpec. [b] Willdenow. [c] Krocker.

open

open air, than within the reach of the ſmoke of London.

The uſual time of theſe ſhrubs producing their flowers is from the middle, or latter end of may, till the middle of july.

But in order to continue theſe beauties longer than they are naturally diſpoſed to laſt, it is proper to plant ſome of the Monthly Roſes near a warm wall, which will occaſion their budding at leaſt three weeks or a month before thoſe in the open air; and, if you give them the help of a glaſs before them, it will bring their flowers much forwarder, eſpecially where dung is placed to the back ſide of the wall (as is practiſed in raiſing early fruits;) by this method I have ſeen fair Roſes of this kind blown in february, and they may be brought much ſooner againſt hot walls or in ſtoves, where people are curious this way.

You may alſo cut off the tops of ſuch ſhoots which have been produced the ſame ſpring early in may, from ſome of theſe ſorts of Roſes which are planted in the open air, and upon a ſtrong ſoil; this will cauſe them to make new ſhoots, which will flower late in autumn, as will alſo the late removing the plants in ſpring, provided they do not ſuffer by drought, as I have ſeveral times experienced; but particularly in the year 1718, when I had occaſion to remove a large parcel of theſe plants in may, juſt as they were beginning to flower; n doing of which I cut off all the flower-buds, and, after having opened a trench where they were to be planted, I poured a large quantity of water, ſo as to render the ground like a pap; then I took up the plants, and placed them therein as ſoon as poſſible, that their roots might not dry; and, after planting them, I watered the ground well again, and covered the ſurface over with mulch to prevent the drying; after this I repeated watering the plants all over two or three times a week, in the evening, until they had taken root. In three weeks or a month after, the plants ſhot out again, and produced a great quantity of flowers in auguſt and ſeptember, which were as fair as thoſe produced in june. The Monthly Roſe is the beſt ſort for this purpoſe, there being no other ſort which will flower both early and late ſo well as this.

The next ſort of Roſe which flowers in the open air, is the Cinnamon, which is immediately followed by the Damaſk Roſe, then the Bluſh, York, and Lancaſter come; after which, the Provence, Dutch Hundred-leaved, White, and moſt other ſorts of Roſes follow; and the lateſt ſorts are the Virginia and Muſk Roſes, which, if planted in a ſhady ſituation, ſeldom flower until ſeptember; and, if the autumn proves mild, will continue often till the middle of october.

The plants of the two ſorts of Muſk Roſes, ſhould be placed againſt a wall, pale, or other building, that their branches may be ſupported, otherwiſe they are ſo ſlender and weak as to trail upon the ground. Theſe plants ſhould not be pruned until ſpring, becauſe their branches are ſomewhat tender; ſo that when they are cut in winter, they often die after the knife; theſe produce their flowers at the extremity of the ſame year's ſhoots in large bunches, ſo that their branches muſt not be ſhortened in the ſummer, leſt thereby the flowers ſhould be cut off. The ſhrubs will grow to be ten or twelve feet high, and muſt not be checked in their growth, if you intend they ſhould flower well, ſo that they ſhould be placed where they may be allowed room.

The loweſt ſhrub of all the ſorts here mentioned is the Scotch Roſe, which rarely grows above a foot high, ſo that this muſt be placed among other ſhrubs of the ſame growth, which ſhould have a moiſt ſoil and a ſhady ſituation. The Red Roſe, and the Roſa Mundi, commonly grow from three to four feet high, but ſeldom exceed that: but the Damaſk, Provence, and Frankfort Roſes grow to the height of ſeven or eight feet; ſo that in planting them, great care ſhould be taken to place their ſeveral kinds, according to their various growth, amongſt other ſhrubs, that they may appear beautiful to the eye.

The Yellow Roſe, and Auſtrian Roſe ſeldom ſhoot ſo ſtrong as moſt of the other ſorts, eſpecially in the light land near London, where they ſeldom produce their flowers. Theſe are eſteemed for their colour, being very different from all the other ſorts of Roſes; but as their flowers have no ſcent, and are of ſhort duration, they do not merit the price they are generally ſold at.

The Frankfort Roſe is of little value, except for a ſtock to bud the more tender ſorts of Roſes upon, for the flowers ſeldom open fair, and have no ſcent; but it being a vigorous ſhooter, renders it proper for ſtocks to bud the Yellow and Auſtrian Roſes, which will render them ſtronger than upon their own ſtocks; but the Yellow Roſes ſeldom blow fair within eight or ten miles of London, though in the northern parts of Great Britain they flower extremely well. This ſort muſt have a northern expoſure, for if it is planted too warm, it will not flower.

The Damaſk and Monthly Roſe ſeldom flower well in ſmall confined gardens, nor in the ſmoke of London, therefore are not proper to plant in ſuch places, though they frequently grow very vigorouſly there. Theſe always begin to ſhoot the firſt of any of the ſorts in the ſpring, therefore frequently ſuffer from froſts in april, which often deſtroy all their flowers.

All the ſorts of Roſes may be propagated either from ſuckers, layers, or by budding them upon ſtocks of other ſorts of Roſes; which latter method is only practiſed for ſome peculiar ſorts, which do not grow very vigorous upon their own ſtocks, and ſend forth ſuckers very ſparingly, or where a perſon is willing to have more ſorts than one upon the ſame plant; but where this is deſigned, it muſt be obſerved to bud only ſuch ſorts upon the ſame ſtock as are nearly equal in their manner of growth; for if there be a bud of a vigorous growing ſort, and others of weak growth budded in the ſame ſtock, the ſtrong one will draw all the nouriſhment from the weaker, and entirely ſtarve them.

If theſe plants are propagated by ſuckers, they ſhould be taken off annually in october, and tranſplanted out either into a nurſery in rows (as hath been directed for ſeveral other ſorts of flowering-ſhrubs) or into the places where they are to remain; for if they are permitted to ſtand upon the roots of the old plants more than one year, they grow woody, and do not form ſo good roots as if planted out the firſt year, ſo there is more danger of their not ſucceeding.

But the beſt method to obtain good-rooted plants is to lay down the young branches in autumn, which will take good root by the autumn following (eſpecially if they are watered in very dry weather,) when they may be taken from the old plants, and tranſplanted where they are to remain. The plants, which are propagated by layers, are not ſo apt to ſend out ſuckers from their roots as thoſe which are from ſuckers, therefore ſhould be preferred before them; becauſe they may be much eaſier kept within compaſs, and theſe will alſo flower much ſtronger. Theſe plants may be tranſplanted any time from october to april; but when they are deſigned to flower ſtrong the firſt year after planting, they ſhould be planted early; though, as I ſaid before, if they are planted late in the ſpring, it will cauſe them to flower in autumn, provided they do not ſuffer by drought.

Moſt of theſe ſorts delight in a rich moiſt ſoil and an open ſituation, in which they will produce a greater quantity of flowers, and thoſe much fairer, than when they are upon a dry ſoil or in a ſhady ſituation. The pruning which they require, is only to cut out their dead wood, and take off all the ſuckers, which ſhould be done every autumn; and if there are any very luxuriant branches, which draw the nouriſhment from the other parts of the plant, they ſhould be taken out, or ſhortened, to cauſe them to produce more branches, if there be occaſion for them to ſupply a vacancy, but you muſt avoid crowding them with branches, which is as injurious to theſe plants as to fruit-trees; for, if the branches have not equal benefit from the ſun and air, they will not produce their flowers ſo ſtrong, nor in ſo great plenty, as when they are more open, and better expoſed to the ſun,

ſo

Digitized by Google

ſo that the air may circulate the more freely between them.

[14. Thoſe little elegant varieties of the Provence Roſe, called greater Roſe de Meaux, and ſmaller Roſe de Meaux or Pompone Roſe, may be increaſed, like moſt of the other ſpecies, by ſuckers, which however are not very plentifully produced in theſe, and do not extend to any great length.

The roots ſhould not be divided oftener than once in three years: if the old wood be cut down every year, after the plants have done blowing, they will throw out more vigorous ſhoots, and flower more freely [d].]

22. The Moſs Provence Roſe rarely ſends up ſuckers, and when the branches are layed down they are long before they put out roots; it is therefore frequently propagated, by budding it upon ſtocks of the other ſorts; but the plants ſo raiſed are not ſo durable as thoſe which are propagated by layers; [and this latter method is now moſt uſually adopted.

DESCRIPTIONS, *&c.*

1. Root ſtrong, woody, fibrous. Stem ſhrubby, covered with a rough gray bark, divided into many branches, and in gardens riſing frequently to the height of eight or ten feet: but in its natural ſtate much lower. Leaves numerous, ſeſſile, linear, entire, blunt, contracted at the edges, dark green above, grayiſh or whitiſh underneath, with ſmall glandular excavations, placed in whorls on the branches. Flowers from the axils of the leaves, from ſix to twelve together, large, pale blue, ſometimes white with blue ſpots and dots. Calyx ſubtomentoſe [e].

Native of the South of Europe, the Levant and Barbary. Its cultivation in this country, like many other plants, is probably of ancient date, though we can now ſeldom trace them beyond the time of Gerarde [f], in 1596. It flowers from january to may.]

Mr. Miller, following the old writers, diſtinguiſhes two ſpecies of the Roſemary, having long cultivated both, and having raiſed them from ſeeds, without finding them to vary. The leaves of the wild are broader than thoſe of the garden Roſemary, and their points are blunter. The flowers are alſo much larger, and of a deeper colour. The ſtalks grow larger, and ſpread out their branches wider; and the whole plant has a ſtronger ſcent.

There are two other varieties; one of the garden ſort, with ſtriped leaves, which the gardeners call the Silver Roſemary: the other, of the wild ſort, ſtriped with yellow, and called Gold-ſtriped Roſemary. The former is ſomewhat tender, and all the plants of this variety were killed in the ſevere winter of 1740. The latter is pretty hardy, and will live in the open air through our common winters, on a dry ſoil.

[Roſemary has a fragrant aromatic ſmell, and a bitteriſh pungent taſte. The leaves and tops are ſtrongeſt in their ſenſible qualities: the flowers ought not to be ſeparated from their calyxes; the active matter reſiding principally, if not wholly, in the latter. Roſemary yields its qualities completely to rectified ſpirit, but only partially to water. The leaves and tops, diſtilled with water, yield a thin light pale eſſential oil of great fragrancy, though not quite ſo agreeable as the Roſemary itſelf. From one hundred pounds of the herb in flower eight ounces of oil have been obtained. The decoction, thus diveſted of the aromatic part of the plant, yields on being inſpiſſated, an unpleaſant bitteriſh extract. Rectified ſpirit likewiſe, diſtilled from Roſemary leaves, become conſiderably impregnated with their fragrance, leaving however in the extract the greateſt ſhare both of their flavour and pungency. The active matter of the flowers is ſomewhat more volatile than that of the leaves, the greateſt part of it ariſing with ſpirit.

Roſemary is reckoned one of the moſt powerful of thoſe plants which ſtimulate and ſtrengthen the nervous ſyſtem: it has therefore been recommended in various affections, ſuppoſed to proceed from debilities, or defective excitement of the brain and nerves; as in certain headachs, deafneſſes, giddineſſes, palſies, &c. and in ſome hyſterical and dyſpeptic ſymptoms.

The ancients were well acquainted with this ſhrub, and it is mentioned by Dioſcorides, Galen and Pliny [*]. It has ever been treated with great reſpect for its efficacy in comforting the brain, and ſtrengthening the memory. Hence the frequent alluſions to this property in our old poets:

"There's Roſemary, that's for remembrance;"

[d] Curtis.

[e] Haller and Woodville. [f] Woodville. [*] Woodville, Lewis.

Digitized by Google

ſays Ophelia to Laertes, in Shakſpeare's Hamlet.—Again, Perdita ſays to Polixenes and Camillo:

——— "Reverend Sirs,
"For you there's Roſemary and Rue; theſe keep
"Seeming and favour all the winter long;
"Grace and Remembrance be to you both:——"

Rue ſignifying Grace, and Roſemary Remembrance.

Its quality of ſtrengthening the memory made Roſemary an emblem of fidelity in lovers. Thus in a ſonnet 1584:

"Roſemary is for remembrance
"Betweene us daie and night;
"Wiſhing that I might alwaies have
"You preſent in my ſight."

It was accordingly worn at weddings: and perhaps on the ſame principle at funerals[g], on which latter occaſions, in ſome parts of England, it is ſtill diſtributed among the company, who frequently throw the ſprigs into the grave along with the corpſe.

Roſemary has the character of being an emmenagogue; and the only diſeaſe in which Bergius ſtates it to be uſeful is the chloroſis. The officinal preparations of it are *Oleum eſſentiale roris marini*, and *Spiritus Roris marini*. It is a principal ingredient in what is known by the name of Hungary water: and the herb is taken as tea by many perſons[h], for headachs and diſorders called nervous[h].

2. This is a ſhrub known only from a ſhort deſcription given by Ignatius Molina. Future obſervations will inform us whether it belong really to this genus or not.—Native of Chili[i].]

PROPAGATION AND CULTURE.

Roſemary thrives prodigiouſly upon dry rocky ſoils near the ſea, in the South of France, in Spain and Italy. It is hardy enough to bear the cold of our ordinary winters in the open air, provided it be planted upon a poor dry gravelly ſoil, or near a wall.

The varieties with ſtriped leaves are ſomewhat tender, eſpecially that with ſilver ſtripes. Theſe therefore ſhould either be planted by a warm wall, or in pots filled with light freſh earth, and ſheltered in winter under a frame.

Roſemary may be increaſed by planting ſlips or cuttings in the ſpring, juſt before the plants begin to ſhoot, upon a bed of light freſh earth: when they are rooted, tranſplant them where they are to remain, about the beginning of ſeptember, that they may take new root, before the froſty weather comes on. If they are not tranſplanted thus early, let them remain unremoved till march following; obſerving to tranſplant them in mild ſhowery weather. They will then require no farther care but to keep them clear from weeds.

When Roſemary is by accident rooted in a wall, it will endure the greateſt cold of our winters, though it be much expoſed to cold winds.

Pist. *Germ* ſuperior, ovate. *Style* filiform. *Stigma* trifid.

Per. *Capſule* ovate, ſubtrigonal, incloſed within the calyx, three-celled, three-valved.

Seeds very many, roundiſh.

ESSENTIAL CHARACTER.

Cal. three-toothed. *Cor.* none. *Capſ.* three-celled, many-ſeeded.

SPECIES.

1. Rotala verticillaris.

Lin. ſyſt. 82. *Reich.* 94. *Willd.* 189. *mant.* 175.

DESCRIPTION, &c.

This is an annual plant, with a ſimple creeping root. Stem aſcending, a palm high, round, jointed, even. Branches quite ſimple, ſtiff; the lower oppoſite, the upper alternate, fewer; the joints below round, above ſomewhat four-cornered. Leaves in fours, ſometimes on the branches from five to eight, ſeſſile, linear, ſharpiſh, even, ſomewhat keeled, ſpreading. Flowers in fours, one from each axil of the leaves, ſeſſile, ſmall. Calyx covering the whole capſule, very finely membranaceous. Fruit the ſize of Muſtard ſeed. Whorls remote.—Native of the Eaſt Indies[k].

Rotang. See *Calamus*.

ROTHIA. (*So named by Schreber in honour of Albrecht Wilhelm Roth, phyſician at Bremen.*)

Lin. gen. Schreb. n. 1241. *Gærtn. t.* 174.

Claſſ. 19. 1. Syngeneſia Polygamia Æqualis.

Nat. order of *Compoſitæ Semiflоſculoſæ. Cichoraceæ*, Juſſ.

GENERIC CHARACTER.

Cal. *Common* rounded, villoſe-tomentoſe: *ſcales* about ſeven, equal, linear, acute.

Cor. *Compound* imbricate, uniform: *Corollets* hermaphrodite, numerous, equal.

Proper one-petalled, ligulate, linear, truncate, five-toothed.

Stam. *Filaments* five, capillary, very ſhort. *Anther* cylindrical, tubular.

Pist. *Germ* ovate. *Style* filiform, the length of the ſtamens. *Stigmas* two, reflex.

Per. none. *Calyx* converging.

Seeds ſolitary.—In the *Diſk* cylindric-turbinate, ſtriated; with a capillary *Down*, feathered below and ſeſſile.—In the *Ray* cylindrical, ſtriated, wrapped up in chaffs; without any *Down*.

Rec. flat, in the diſk hairy, in the ray chaffy. *Chaffs* in ſeveral rows, linear, channelled, erect, ſharpiſh, tubular at the baſe: outer the length of the calyx; inner gradually ſhorter.

Obs. *It is very nearly allied to* Andryala.

ESSENTIAL CHARACTER.

Cal. many-leaved in a ſingle row, equal, woolly. *Recept.* in the ray chaffy, in the diſk villoſe. *Seeds* in the ray bald, in the diſk pappoſe.

SPECIES.

1. Rothia andryaloides.

Voigtia. *Roth diar. botan. tigur.* 1790. *n.* X. *p.* 17.

ROTTBOELLIA. (*So named by the younger Linnæus, in memory of Chriſtian Friis Rottboell, profeſſor of botany, at Copenhagen.*)

Lin. fil. nov. gen. gram. 23. *ſuppl.* 13. *Schreb. gen. n.* 1573. *Juſſ.* 31.

Claſſ. 23. 1. Polygamia Monoecia—v. 3. 2. Triandria Digynia.

Nat. order of *Gramina, Gramineæ* or *Graſſes*.

GENERIC CHARACTER.

Receptacle *common* elongated into the jointed rachis of a cylindrical ſpike: the joints alternately hollowed out to receive flowers of a two-fold ſtructure: *ſome* (in the calyx) one-glumed, placed on a thicker tooth, hermaphrodite; *others* two-glumed, each inſerted (alternately) on either ſide of the former, a little lower down, and a little ſmaller than the former, female hermaphrodites? in ſome ſpecies only one of each ſort.

* *Hermaphrodites, one-glumed.*

Cal. *Glume* one-flowered, one-valved: *valve* cartilaginous, ovate-oblong, truncate at the baſe, often emarginate, ſtriated, cloſing the ſinus of the joint (which is in place of a ſecond valve) like a lid.

Cor. *Glume* two-valved, parallel to and ſhorter than the calycine glume: *valves* lanceolate, acute, concave, membranaceous, hyaline: outer longer, inner with the edges bent in.

Nectary one-leafed, lanceolate, blunt, membranaceous, hyaline, longer than the germ.

[g] See notes on Shakſpeare, Steevens's edit. vol. 15. p. 275.

STAM. *Filaments* three, capillary. *Anthers* oblong, bifid at each end.

PIST. *Germ* oblong. *Styles* two, filiform. *Stigmas* oblong, feathered, ſpreading, ſtanding out.

PER. none. The ſinuſes of the joints of the ſpike cloſed by the glume of the calyx contain the ſeed, until the rachis ſeparates in joints.

SEED ſingle, oblong.

* *Hermaphrodites? two-glumed.*

CAL. *Glume* one-flowered, two-valved, tranſverſe: *valves* cartilaginous, oblong, mucronate, ſtriated; outer a little ſhorter, with a ſhorter dagger-point.

COR. *Glume* two-valved, tranſverſe: *valves* lanceolate, membranaceous, ſhorter than the calyx; outer concave, longer, inner with the edges folded together.

Nectary as in the other; or two-leaved, with the leaflets lanceolate, acuminate.

STAM. *Filaments* three, capillary. *Anthers* oblong, bifid at each end.

PIST. *Germ* oblong or ovate. *Styles* two, capillary. *Stigmas* oblong, feathered, ſpreading, ſtanding out.

PER. none. Calyx and corolla cheriſh the ſeed, faſtened to the rachis, which ſeparates in joints.

SEED ſingle, ovate or oblong.

OBS. *Flowers of both ſtructures are found in* R. exaltata, corymboſa, *and others: one-glumed only in* R. cylindrica *and* compreſſa; *two glumed only in* R. incurvata. *Where both are preſent, both ſeem to be hermaphrodite; unleſs perhaps in the*[a], *the two-glumed flowers may have the anthers barren, for there does not ſeem to be any defect in the ſtyles and ſtigmas. If flowers of either ſort only be preſent, they are hermaphrodites. This genus therefore, in other reſpects very nearly allied to Ægilops, might have been put with the other Graſſes in the ſecond order of the third claſs,* Triandria Digynia. — *Schreber obſerved a two-leaved nectary in* R. incurvata *alone.*

ESSENTIAL CHARACTER.

Rachis jointed, roundiſh, in moſt ſpecies filiform. *Cal.* ovate-lanceolate, flat, one or two-valved. *Florets* alternate on a flexuoſe rachis.

DESCRIPTIONS, &c.

1. Culms branched, procumbent at the baſe, jointed, knobbed. Leaves ſmooth, wide. Spikes ſlender: rachis flexuoſe, knobbed, ſtriated, alternately excavated. Flowers ſolitary, ſeſſile, preſſed cloſe. Outer calyx two-flowered, one-glumed; glume coriaceous, two-parted, awl-ſhaped, ſegments converging at the edge and equal: inner calyx membranaceous, two-glumed, ſhorter, awnleſs: one of the flowers commonly abortive[1].

Culm branched. Spikes linear, rigid, curved inwards, having as far as fourteen joints. At each joint is a ſpikelet, with a two-glumed calyx; the glumes equal, acuminate, awnleſs, one-flowered. Petals two, acuminate, thin, twice as ſhort as the calyx; one of them bifid. Filaments ſhorter than the petals, with fulvous anthers. Germ fulvous[a].—Scopoli did not

[1] Desfontaines. [a] Scopoli.

find

Digitized by Google

find a three-flowered calyx, and male flowers mixed with the hermaphrodites.

Calycine glume ſolitary, undivided, for the flowers being faſtened to the rachis, a ſecond glume is not wanting. The caſe is the ſame in Lolium [n].

Root annual, fibrous, very much branched, elongated. Culms numerous, decumbent at the baſe, branched, jointed, round, very ſmooth, leafy. Leaves ſpreading, linear, acute, flat, ſtriated, rugged above and at the edge. Sheaths ſhorter than the leaves, ſomewhat ſwelling, ſtriated, ſmooth. Stipule ſhort, blunt. Spike ſolitary, filiform, ſomewhat bowed, round, ſmooth, many-flowered. Rachis jointed, alternately excavated; joints one-flowered. Calyx two-glumed: glumes lanceolate, acute, awnleſs, ſmooth, ſtriated, parallel, tightly cloſely each excavation, but ſpreading in flowering time. Floret ſolitary, hermaphrodite, a little ſhorter than the calyx: glumes membranaceous, white, awnleſs, nearly equal [o].

Native of many parts of Europe, on the ſea coaſt, and in ſalt-marſhes. In England, near Yarmouth and Sheringham in Norfolk. Wiſbech in Cambridgeſhire. Near Seaton, in Durham. Below King's Weſton, near Briſtol. At Exmouth, in Devonſhire. It flowers in july and auguſt.

2. This reſembles the preceding very much, but differs from it in having the culm more ſlender and purple; the leaves of a darker green, three times ſhorter and narrower, more acuminate, and channelled, not bright green and flat, above more ſtriated and rugged; the ligule almoſt three times as long, inſtead of being very ſhort ſcarcely the quarter of a line in length, retuſe; the ſpike as ſlender again; the florets more approximating, ſo as to be almoſt contiguous, and ſmaller; the glumes twice as ſmall and blunter, not lanceolate-acuminate.—Native of the South of Europe [p]. Perennial.

3. Culm erect, even, branched, alternately compreſſed and channelled from one knot to another. Leaves ſmooth; with a ſheath ſhorter than the internodes. Spikes three to ſix, in bundles, axillary, peduncled. Peduncles involved in the ſheath, preſſed cloſe. Several acute membranes come out from each knot. Spikes bowed, ſmooth. Flowers diſpoſed in four rows, cloſe preſſed. Outer calyx one-flowered, one-glumed; glume coriaceous, ovate, compreſſed, ſubacute. Inner calyx two-glumed, membranaceous, awnleſs, ſhorter. Rachis jointed, excavated in four rows [q].—Native of the South of Europe, and of Barbary. Perennial.

4. Culms minute, erect, compreſſed, about an inch high without the ſpike, and two with it. Leaves numerous, forming a tuft, two inches long, briſtle-ſhaped. Spike ſolitary, erect, awl-ſhaped, two-ranked, compreſſed, yellowiſh: rachis waved, excavated on the ſides, not jointed. Flowers all hermaphrodite, diſpoſed alternately in the excavations of the rachis. Calyx one-flowered, two-valved: outer valvelet rigid, linear; inner boat-ſhaped and leſs rigid. Corolla two-valved, membranous, hairy.—Found by Koenig in Tranquebar, at St. Thomas's mount; on old walls [r].

Willdenow has diſtinguiſhed another ſpecies, found alſo by Koenig in Malabar, which ſeems to be the ſame with this. He thus deſcribes it under the name of *R. piloſa*. It is the ſmalleſt ſpecies of the genus. The whole graſs being hardly more than an inch in height. Culms ſimple, cloſely covered with the ſheaths of the leaves, ſeveral from one root. Leaves linear, channelled, hairy with ſcattered hairs long in proportion to the plant. Spike ſolitary, terminating, awl-ſhaped.

5. Native of the iſlands in the South Seas within the Tropics [s].

6. Culms aſcending, leafy, having a ſheath to the ſecond or third joint, whence ſpring three or four one-ſpiked peduncles more than a foot long. The lower joint of theſe is almoſt triangular or elſe ſemicylindrical, and hollowed, but the upper one, which bears the ſpike, is exactly cylindrical, and is wrapped up about half way in the ſheath. Leaves ſhort, keeled, bearded at the edges. Spike very ſtiff, and in each joint of it two lateral alternate flowers. Outer glume of the calyx obliquely ovate, cartilaginous, quite ſmooth and even: inner glume equal, membranaceous, very thin, as is alſo the corolla.—Sent by Koenig from Tranquebar.

7. Culms compreſſed, leafy. Leaves even, naked, with compreſſed ſheaths. From the upper ſheaths of the culm comes out a peduncled and involucred bundle of ſpikes. Spikes in this involucre again peduncled, and having a partial ſheathed involucre at the baſe. Each ſpike compreſſed flat on one ſide. At each joint are two flowers, the calyxes of which are acute, awnleſs, undotted; each two-valved, but one oppoſite, with both valves cartilaginous, narrower, longer, and in a manner awned; the other lateral, with the inner valve membranaceous and together with the corolla concealed by the outer valve in the hollow of the rachis.—Tranchell found it in China [t]. Native both of the Eaſt and Weſt Indies.

8. Culm a foot high and more, ſtriated, alternately excavated at top. Flowering branches ſometimes ſeveral from one joint. Leaves involute, ſtiffiſh, two inches long, yellowiſh at the tip, the uppermoſt ſpathaceous. Sheaths wider than the leaves, ſomewhat grooved, bearded at the mouth. Spike ſolitary, three or four inches long. Rachis flexuoſe, jointed; one ſide convex, the other concave where the florets are, the whole ſet with a ſoft ſilky hairineſs, except the hollow ſide; each tooth two-flowered: one of the flowers ſeſſile, ſpreading, the other pedicelled, preſſed cloſe: ſometimes there are three to each tooth, and then the middle one is pedicelled. Glumes two-valved, ovate, two-flowered: valves unequal; outer flat, ciliate with long hairs, rolled in at the edge, acuminate, point bifid with the ſegments unequal; inner convex, keeled, hairy on the back and at the end, acute, entire. One corolla male, the other hermaphrodite: valves lanceolate, hyaline. The pedicelled flower is barren: valves lanceolate, unequal, ciliate, entire [u].

Native of Egypt. Perennial. A beautiful Graſs.

9. This is a ſlender graſs, a foot high. Culms ſeveral ſimple and branched; the latter having one leaf, the former none. Leaves ſhort, thin, ciliate at the edge above the ſheath with long, diſtinct, white hairs: ſheath truncate, with a pale-brown mouth, ciliate. Spikes two, linear, an inch and half long and a line wide, ſome hermaphrodite, others female: rachis linear, membranaceous, behind flat with three longitudinal ſtreaks, in front alternately and flexuoſely hollowed. In the hermaphrodite two-glumed florets, both valves are preſſed cloſe to the rachis and parallel to it, but not concealed one by the other: outer valves linear, blunt, ciliate at the back; inner of the ſame length, half-ovate, acute, boat-ſhaped, very much compreſſed, ſtriated, coloured, ciliate at the back, incloſing the corolla, which is hyaline and leſs than the calyx. Anthers black. Germ minute. Stigmas black-bearded. In the female florets, the calyx is one-valved, ovate, ſlightly bifid at the end, ciliate on the edge, oppoſite to the rachis, preſſed cloſe. Corolla none. Piſtil like thoſe of the others, but the ſtigmas ſeem to be longer. Native of Bengal, where it was obſerved by Koenig [x].

10. Native of the iſland of Tanna [y].

11. Native of the Eaſt Indies, in ſandy ſoils [z], and of the Cape of Good Hope [a].

12. This is a tall graſs, with a ſolid culm. Sheaths of the leaves grooved, dotted with raiſed dots, ending in a briſtle, hiſpid all over. Spikes ſolitary, lateral, a hand long or more [b].

Swartz thus deſcribes under the ſame name a Graſs which he found in Jamaica. Culm from two to ſix feet high, upright, ſubdivided, ſtriated, ſemicylindrical, ſheathed; branchlets upright. Leaves a foot long, broad-linear, ſpreading, even, cartilaginous-ſerrate at the edge. Sheaths two or three inches in length, ſtriated, dotted, hiſpid-hirſute, rough-haired at the mouth: hairineſs thin, white, pungent. Spikes

[n] Cyrillo. [o] Smith. [p] Roth in Willdenow. [q] Desfontaines. [r] Roxburgh. [s] Forſter. [t] Retzius. [u] Vahl. [x] Retzius. [y] Forſter. [z] Linn. ſuppl. [a] Thunb. prodr. [b] Linn. ſuppl.

ſolitary,

Digitized by Google

ſolitary, two or three inches long, cylindrical, jointed, acuminate, even, green. Florets ſeſſile, alternate: rachis flexuoſe, with excavations for the florets, which form a round ſpike. The exterior flowers are male, the interior hermaphrodite, within the ſame calycine glumes. Glume two-valved, two-flowered: outer valve ovate, acute, preſſed cloſe to the ſpike; inner arched involving the hermaphrodite flower. Corolla of the male flower two-valved: valves ſmaller, white. The nectary conſiſts of two truncate petals at the baſe of the filaments. Anthers red, fertile; they are often barren, and then are yellow. Piſtil none. Hermaphrodite within the male, and not viſible unleſs that be removed. The corolla of the hermaphrodite is alſo two-valved; the valves whitiſh and fugacious. Anthers often barren. Germ roundiſh. Stigma villoſe, purple. After the male flower falls, the ſeed ripens within the rachis, and when ripe falls off, the ſpike breaking.

13. Culm cylindrical, full, leafleſs. Spike ſhorter than a finger, ſtiff, coming out in bundles from the upper ſheaths of the culm, and ſheathed themſelves. Florets placed in an alternate row, ſolitary. Calyx ovate, blunt, ſtreaked and dotted[c].—Native of Malabar, in ditches.

14. Culms angular, leafy; with ciliate ſheaths. All the calyxes very ſlightly pubeſcent; the lateral wider, ſcarioſe at the top, ciliate-prickly at the edge; the oppoſite a little lower, ſmaller, ſcarcely ciliate, empty. In this and in *compreſſa*, one calyx is lateral, the other oppoſite, in *corymboſa* and *lævis* they are all lateral[d].—Native of the Eaſt Indies.

15. This has altogether the appearance of an Andropogon. Culm half-round, jointed, leafy. Sheaths widening at top, and almoſt cowled over the upper joints. From each ſheath iſſues a filiform ſheath, the peduncle of which is concealed within the ſheath. Flowers ſeſſile, alternate, along the excavated rachis. Calyx two-valved obliquely lateral; the outer glume ſemicylindric awl-ſhaped, cartilaginous; the inner equal, very thin, white with blood-red ſtreaks. Outer glume of the corolla blood-red, the length of the inner calycine glume: inner glume cloven to the very baſe, ſo that there ſeems to be inner glumes, of a lanceolate form, half white and half red, very finely ciliate: at the baſe of this is a long twiſted awn. Bracte next the flower linear, cartilaginous, ſlightly awned, ciliate-bearded on one ſide, alternate. Anthers and ſtigmas blood-red. If the bracte be aſſigned to the calyx, and the inner petal be conſidered as double, then the calyx and corolla will be three-glumed, with unequal glumes, which is ſingular. Perhaps this graſs may be of a diſtinct genus; the habit certainly is different. Native of China, whence it was ſent by Bladh[e].

16. Culms many, erect, ramous, filiform, ſmooth, from two to ſix inches high. Leaves a little hairy on the inſide. Spike about an inch or an inch and half long. Flowers all hermaphrodite, imbricate on the excavated ſide of the rachis. Calyx one-flowered; valves equal, membranaceous-margined. Corolla two-valved, membranaceous, hairy.

Native of the Eaſt Indies, on old walls[f].—See the deſcription from the Supplement of the younger Linneus, under *Nardus indica*.

17. Roots capillary, numerous; whence ſpring ſeveral culms half a foot high, having three reddiſh knots at bottom. Root-leaves ſhort, very narrow: ſtem-leaves ſheathing the culm for an inch and half in length: thence erect and briſtle-ſhaped. Flowers ſolitary, or in pairs, one ſeſſile, the other peduncled; all in the alternate excavations of the rachis. Glume of the calyx ſolitary, very ſhort, red, ovate-acute. Corolla two-valved: valves ſmooth, nearly equal, oblong, keeled, acute; the outer embracing the inner, and terminated by an awn equal to the valve itſelf. Stamen one only: filament between the germ and the awned valve, villoſe at the baſe: anther oblong, four-grooved, blackiſh-purple, after fecundation deeply bifid. Germ turbinate. Styles two. Stigmas revolute, feathered. Seeds ſolitary, concealed within the valves. It is an annual graſs, very common about Madrid, and flowers in may. At the top of the ſtem there is always a ſolitary flower, which beyond the calycine glume bears another almoſt oppoſite to that and much ſhorter[g].

ROUSSEA. (*So named by J. E. Smith, M. D. in memory of the celebrated* Jean Jacques Rouſſeau, *who wrote very elegant Letters on the ſubject of Botany, and cultivated and adorned that lovely ſcience with his laſt breath. Linneus, who frequently correſponded with him, had in his manuſcripts conſecrated a plant to his name: but the younger Linneus having, by miſtake, publiſhed that under the name of* Ruſſelia, *Dr. Smith gave this new, beautiful and very ſingular genus the name of* Rouſſea.

Smith, ic. ined. 1. 6.

Claſſ. 4. 1. Tetrandria Monogynia.

GENERIC CHARACTER.

CAL. *Perianth* four-cleft, ſmooth: *ſegments* tongue-ſhaped, acute, reflex.

COR. bell-ſhaped, wrinkled on the outſide, ſubpubeſcent, half-four-cleft: *ſegments* acute, revolute.

STAM. twice as long as the revolute corolla, and alternate with its ſegments. *Filaments* ſtraight, very wide, a little narrower at the top, ſmooth. *Anthers* ſmall, ſagittate, acute.

PIST. *Germ* ſuperior, quadrangularly pyramidal, ſmooth. *Style* the length of the ſtamens, permanent. *Stigma* ſimple, blunt, umbilicate-depreſſed, ſmooth.

PER. *Berry* quadrangularly pyramidal, one-celled, with a ſmooth hard bark.

SEEDS very numerous, ſmall, lens-ſhaped, neſtling.

ESSENTIAL CHARACTER.

Cal. four-leaved. *Cor.* one-petalled, bell-ſhaped, four-cleft, inferior. *Berry* quadrangular, many-ſeeded.

SPECIES.

1. Rouſſea ſimplex.

Smith, ic. ined. 1. 6. *Willd. ſpec.* 607.

DESCRIPTION, *&c.*

This is a ſmall ſhrub, climbing over trees or rocks, ſeemingly among moſs. Stem and branches thick, fleſhy, knobbed. Leaves oppoſite, petioled, obovate, acute or ſubacuminate, toothed, very ſmooth on both ſides, ſomewhat fleſhy. Stipules intrafoliaceous, membranaceous, acute. Flowers ſolitary, axillary, on ſhort peduncles, nodding, large, of a very fleſhy ſubſtance. Bractes cluſtered, membranaceous, acute, like the ſtipules. Peduncles round, naked.—Found by Commerſon in the iſland of St. Mauritius; and communicated by Monſ. Thouin[h].

ROXBURGHIA. (*Named in honour of* William Roxburgh, *M. D. born in Scotland, and ſettled in the Eaſt Indies; author of a ſplendid work on the plants of the coaſt of Coromandel.*)

Roxb. corom. 1. *t.* 32.

Claſſ. 8. 1. Octandria Monogynia.

GENERIC CHARACTER.

CAL. inferior, four-leaved: *leaflets* lanceolate, membranaceous, ſtriated, coloured, revolute, immediately below the petals.

COR. *Petals* four, nearly erect, lanceolate, the lower half rather broader than the upper, along the inſide runs a deep, ſharp, ſlightly waved keel, forming on each ſide a deep groove or hollow; the four keels converge, and in ſome meaſure adhere together, thus bringing the ſide of the petals cloſe, and forming a tube: the upper part of the petals is narrow, bending out a little, and then their points bend in.

Nectary compoſed of four, lanceolate, yellow bodies, each ſeſſile on the apex of the keel of the petals, converging into one conical body.

STAM. *Filaments* none. *Anthers* eight, linear, lodged in the grooves formed by the keel of the petals, adhering their whole length, but their chief inſertion near the baſe.

[c] Retzius. [d] Idem. [e] Idem. [f] Roxburgh. [g] Cavanilles. [h] Smith.

Digitized by Google

PIST. *Germ* ſuperior, heart-ſhaped. *Style* none. *Stigma* pointed.

PER. *Capſule* ovate, compreſſed, one-celled, two-valved, opening from the apex; about an inch and half long, and an inch broad.

SEEDS from five to eight, inſerted by pedicels into the bottom of the capſule, cylindric, ſtriated; the pedicels ſurrounded with numerous ſmall pellucid veſicles.

ESSENTIAL CHARACTER.

Cal. four-leaved. *Cor.* four-petalled, inwardly keeled. *Nect.* four awl-ſhaped (lanceolate, *W.*) leaflets, on the apex of the keel of the petals, (inſerted in the middle of the petals, *W.*) converging. *Anthers* (in pairs, *W.*) linear, ſeſſile, in the grooves of the keel, (hanging down from the baſe of the leaflets of the nectary, *W.*) *Capſ.* one-celled, two-valved. *Seeds* many, inſerted in a ſpongy receptacle.

SPECIES.

1. Roxburghia glorioſoides.

Roxb. corom. 1. *p.* 29. *n.* 32. *t.* 32. *Willd. ſpec.* 321.

DESCRIPTION, *&c.*

Root perennial, compoſed of many ſmooth, cylindric fleſhy tubers, from ſix to twelve inches long, and from three to five in circumference about the middle; they taper equally towards each end. Stem biennial or more, twining, ſmooth, from ſix to twenty feet long, running over ſmall trees, &c. Branches like the ſtem, but few and more ſlender. Leaves alternate or oppoſite, nearly depending, heart-ſhaped, fine-pointed, the point recurvate; entire, ſmooth, ſhining, in ſubſtance ſoft and delicate, generally eleven-nerved, with beautiful very fine tranſverſe veins running between the nerves, from four to ſix inches long, and three or four broad. Petiole ſlightly channelled, ſmooth, an inch and half or two inches broad. Peduncle axillary, ſingle, erect, the ſame length with the petiole, generally two-flowered. Pedicels club-ſhaped, ſhort. Bracte one, lanceolate, at the baſe of the pedicels.

Native of Coromandel, in moiſt valleys among the mountains; flowering in the cold ſeaſon. It is the *Canipoo-Tiga* of the Telingas[l].

Willdenow remarks, that this is a ſingular plant between the *Liliaceæ* and the *Aſclepiadeæ*, that the root is fuſiform, the ſtem grooved, the branches alternate; that there are two bractes at the diviſion of the peduncle; that the calyx is yellow and larger than the corolla, which is purple.]

ROYĒNA. (*Named by Linneus, in honour of* Adrian van Royen. *He, and his ſon David, were ſucceſſively profeſſors of botany at Leyden.*)

Lin. ſpec. ed. Willd. 633.

Leaves lanceolate acute ſomewhat hairy underneath.]

DESCRIPTIONS, *&c.*

1. Height eight or ten feet, putting out branches on every ſide. Leaves alternate, ſhining, continuing all the year. Flowers from the wings of the leaves along the branches, having little beauty.

[Fruit a Berry, covered with the permanent calyx, which is coriaceous, torn, and ſtriated within, globular, ſmooth, red above, pale below, four-celled. Fleſh or pulp firm, whitiſh, almoſt like that of the Apple. Cells filled with a pulp clear like glaſs, and not inveſted with any proper membrane, two of them commonly abortive, compreſſed, creſcent-ſhaped. Seeds ſolitary, and two or four in all: thoſe oblong, ſubtriquetrous; theſe elliptic, plano-convex, ſmooth, ſomewhat ſhining, dun-coloured, with a navel at the top, and in this very part marked with a depreſſed line, drawn through the back and belly; they are involved in gelly, and faſtened to the apex of the partitions.

In Commelin's figure, the berry is repreſented too ſmall, and furniſhed with an apex. The pellicle which he attributes to the ſeeds can be nothing elſe but the gelly of the ſeeds dried. Linneus's deſcription of the fruit, from this figure, is erroneous[k].

This and all the other ſpecies are natives of the Cape of Good Hope. This was introduced by Mr. Bentick in 1690. It flowers in may and june[l].

2. This reſembles the preceding, but the branches are villoſe. Leaves elliptic or oblong, cordate at the baſe, tomentoſe underneath, bluntiſh, on ſhort villoſe petioles. Flowers axillary, nodding, ſolitary, on villoſe peduncles the length of the flowers. Bractes two, oppoſite, ovate acute, pubeſcent, larger than the calyx and immediately under it, deciduous[m].

Introduced in 1774, by Mr. William Malcolm[n].

3. Found at the Cape by Thunberg.]

4. This riſes with a ſhrubby ſtalk, five or ſix feet high, ſending out many ſlender branches, covered with a purpliſh bark. Leaves leſs than thoſe of the Box-

[l] Roxburgh.

[k] Gærtner. [l] Hort. kew. [m] Linn. ſyſt. [n] Hort. kew.

tree,

Digitized by Google

tree, entire, of a lucid green, and continuing all the year. The flowers come out from the wings of the leaves round the branches, and are white. Fruit roundiſh, purple, ripening in the winter.

[Cultivated in 1731, by Mr. Miller. It flowers in ſeptember*.]

5. This riſes with a ſtrong woody ſtalk ſeven or eight feet high, covered with a gray bark, ſending out many ſmall branches alternately. Leaves about an inch long, and a quarter of an inch broad in the middle, covered with ſoft hairs. The flowers come out on ſhort peduncles from the ſide of the branches; they are of a worn-out purple colour and ſmall. They appear in july, but are not followed by ſeeds in England.

[It appears in the ſeventh edition of the Dictionary in 1759: but according to the Kew catalogue it was introduced in 1767, by Mr. William Malcolm.

6. This was found at the Cape by Thunberg, and differs in the diſpoſition of the flowers from the other ſpecies

7. This alſo is very different from all the ſpecies hitherto known, in having narrow lanceolate leaves, ſharp at both ends, and ſomewhat hairy underneath. It is a native of the ſame country with all the reſt.]

PROPAGATION AND CULTURE.

Theſe plants are too tender to live through the winter in the open air in England, they muſt be removed therefore into the greenhouſe in autumn, and treated in the ſame way as Orange-trees. The firſt and fifth ſorts are difficult to propagate here, for the branches which are laid down ſeldom put out roots, and thoſe which do are two or three years before they make roots ſufficient to tranſplant, and their cuttings very rarely ſucceed. The beſt time to plant the cuttings is early in the ſpring. Plant them in ſmall pots filled with loam, and plunge them into a very moderate hot-bed; cover them down with hand-glaſſes, and refreſh them with a little water, every eighth or tenth day. If the cuttings ſhoot, inure them gradually to bear the open air, and when they are well rooted, plant each in a ſeparate ſmall pot, and afterwards treat them as the old plants.

If the plants put out any young ſhoots from the bottom, lay them carefully down whilſt young; ſlitting them, as is practiſed in laying Carnations. During warm weather water them frequently but gently; in cold weather ſparingly. When they are rooted, take them off, and treat them in the ſame manner as the cuttings.

The fourth ſort is very apt to ſend up ſuckers from the roots, and may be increaſed that way. When it does not, the branches may be laid down. The cuttings alſo ſucceed much more eaſily than in the others.

DESCRIPTIONS, &c.

1. Dyer's Madder has a perennial root, and an annual ſtalk. The root is compoſed of many long, thick, ſucculent fibres, almoſt as large as a man's little finger; theſe are joined at the top in a head, like the roots of Aſparagus, and ſtrike very deep into the ground, being ſometimes more than three feet in length. From the upper part (or head of the root) come out many ſide roots, which extend juſt under the ſurface of the ground to a great diſtance, whereby it propagates very faſt; for theſe ſend up a great number of ſhoots, which, if carefully taken off in the ſpring, ſoon after they are above ground, become ſo many plants. Theſe roots are of a dark colour on their outſide, ſomewhat tranſparent, and have a yelloviſh red pith in the middle, which is tough and of a bitteriſh taſte; from the root ariſe many large, four-cornered, jointed ſtalks, which in good land will grow five or ſix feet long, and, if ſupported, ſometimes ſeven or eight; they are armed with ſhort herbaceous prickles, and at each joint are placed five or ſix ſpear-ſhaped leaves, about three inches

* Hort. kew.

R U B

inches long, and near one broad in the middle, drawing to a point at each end; their upper ſurfaces are ſmooth, but their midribs on the under ſide are armed with rough herbaceous ſpines; the leaves ſit cloſe to the branches in whorls. From the joints of the ſtalk come out the branches, which ſuſtain the flowers; they are placed by pairs oppoſite, each pair croſſing the other; theſe have a few ſmall leaves toward the bottom, which are by threes, and upward by pairs oppoſite; the branches are terminated by looſe branching ſpikes of yellow flowers, which are cut into four ſegments reſembling ſtars. Theſe appear in june, and are ſometimes ſucceeded by ſeeds which ſeldom ripen in England.

[Leaves four, five or ſix. Flowers four, five or ſix-cleft [p]. Native of the South of Europe, the Levant, and Africa.—Cultivated by Gerarde, in 1597 [q].]

It is well known that Madder is ſo eſſential to dyers and callico-printers, that neither buſineſs can be carried on without it. The conſumption of it is ſo great in England, that upon a moderate computation, more than one hundred and eighty thouſand pounds ſterling is annually paid for what is imported from Holland. This might be ſaved to the public, if a ſufficient quantity of Madder were planted in England, where it might be cultivated to greater advantage than in Holland, our lands being better adapted to the growth of this plant.

[The cultivation of Madder has been ſeveral times attempted, when our commerce with Holland has been interrupted, or the Dutch have raiſed the price of the commodity enormouſly. At the end of the 17th century, Madder was worth about ſix pounds the hundred weight. The quantity imported from Holland being ſix hundred and fourteen tons and an half; ſuppoſing that all together, ſome being better, ſome worſe, it was worth five pounds the hundred on an average; the ſum paid the Dutch for Madder was 61,450l. It was planted near Wiſbech, and they cured a great deal there; upon which the Dutch ſold theirs ſo low as forty ſhillings the hundred, by which means our planters were ſo diſcouraged as to lay their plantations by [r].

The dearneſs of Dutch Madder, induced Mr. Miller, in the year 1758, to publiſh a quarto pamphlet on the cultivation of this uſeful plant, with figures of it, and of the ſtoves, kilns, drying-houſes and mills, uſed by the Dutch in preparing the root; but I believe the culture was not carried to any great extent, and was ſoon dropped.

Since that time, the Society for the Encouragement of Arts, Manufactures and Commerce have taken up the Culture of Madder; and inform the public, in the firſt volume of their Tranſactions, publiſhed in 1783, that Madder having been raiſed to an extravagant price by the foreign growers and importers, on a ſuppoſition that it could not be brought to any degree of perfection in this kingdom, conſiderable premiums were given, to the amount of fifteen hundred pounds and upwards, beſides two gold medals, to encourage its growth here; and that the commodity produced in conſequence, was found as good at leaſt, if not better, than any imported. By theſe premiums, fixing the tithes at five ſhillings an acre, and continuing the rewards, foreign Madder was reduced to a reaſonable price, and may probably continue ſo, unleſs other cauſes ſhould operate to make it dearer; as the foreign growers are convinced that we can ſupply ourſelves with any quantity, and of the beſt kind, whenever, by an advance of the price, the profits are found ſufficient to engage the attention of our huſbandmen.

A ſudden fall however in the price, although it be advantageous to the manufacturer, is a great injury, if not ruin to the grower, who has been at conſiderable expenſe in raiſing and preparing it. Accordingly Mr. Young, in 1784, ſays:—it was with great regret I found, that the extraordinary fall in the price of Madder of cent per cent, had totally deſtroyed all the plantations, which were once ſo flouriſhing in the neighbourhood of Feverſham in Kent; and was exceedingly concerned to hear, that Mr. Crowe, who had gone greater lengths, and made more ſpirited exertions in that culture, than any other man in England, had ſuffered very deeply in his property, by that ruinous decline [s].

Mr. Young, in his tour through the Eaſt of England, made in the year 1770, gives a detailed account of the experiments of John Arbuthnot, Eſq. of Ravenſbury, on the ſubject of Madder, begun in the year 1765; by which it appears that a clear profit of ſeven guineas an acre was made by it, and that inſtead of exhauſting, it ameliorates and cleans the ſoil to a great degree. But if fourteen years after this time, Mr. Crowe was obliged to give up the culture of Madder, it is probable that Mr. Arbuthnot did not find it ſo profitable as it was at firſt, when Madder ſold for 4l. 10s. the hundred weight.

This plant, with others of the ſame natural order, appears to differ from other ſubſtances uſed for the purpoſe of dying, in having the property of tinging with a florid red colour, not only the milk, urine, &c. but even the bones of thoſe animals which have fed upon it; a circumſtance which was firſt noticed by Antonius Mizaldus, but not known in England till Mr. Belchier publiſhed an account in the Philoſophical Tranſactions of a pig and a cock, whoſe bones became red by eating Madder mixed with their food. Since that time various experiments have been made, from which it appears that the colouring-matter of Madder affects the bones in a very ſhort time, and that the hardeſt part of them firſt receives the red colour, which gradually extends from the outſide through the whole bony ſubſtance, ſo long as the animal continues to take the Madder; but if this root be alternately given and intermitted for a ſufficient length of time and at proper intervals, the bones are found to be coloured in a correſpondent number of concentric circles.

Madder is frequently mentioned by the Greek writers, who employed the roots with the ſame medicinal intentions for which they are now recommended by modern writers on the Materia Medica. They have a bitteriſh ſomewhat auſtere taſte, and a ſlight ſmell not of an agreeable kind. They impart to water a dark red tincture; to rectified ſpirits, and to diſtilled oils, a bright red; both the watery and ſpirituous tinctures taſte ſtrongly of the Madder.

By medicinal writers Madder has been conſidered as a deobſtruent, detergent and diuretic, and is chiefly uſed in the jaundice, dropſy and other diſeaſes ſuppoſed to proceed from viſceral obſtructions, particularly thoſe of the liver and kidneys. Some modern writers have recommended it as an emmenagogue, and in rickety affections. With regard to its diuretic quality, Dr. Cullen aſſerts, that in many trials, this is not conſtant. As a remedy for the jaundice, it has the authority of Sydenham, and it was formerly an ingredient in the *decoctum ad icteros* of the Edinburgh Pharmacopœia; but as it ſeemed more adapted to the *fæces albidæ* than to the diſeaſe itſelf, this decoction was expunged. That ſome French writers ſhould preſcribe Madder in a rickety ſtate of the bones, appears ſurpriſing; ſince brute animals, to which it was given, eſpecially the younger, were conſiderably emaciated and weakened by its effects. Its virtues as an emmenagogue reſt principally upon the authority of Dr. Home, who gave from a ſcruple to half a dram of the powder, or two ounces of the decoction, three or four times a day. But this medicine failed with Dr. Cullen; who alſo ſays, "I know of other practi- "tioners in this country, who after ſeveral ineffectual "trials made with it, have now entirely deſerted "its uſe [t]."

2. Stems round, even, decumbent. Leaves in fours, ovate, rugged. Flowers white, ſolitary, peduncled, in the axils of the leaves. Berries roundiſh, red.—Native of Chili [u].

3. Root perennial, branched, penetrating deeply into the fiſſures of rocks; its outer bark red. Stems ſeveral, branched, diffuſed, four-cornered, the corners

ſet

Digitized by Google

ſet with prickles pointing backwards; not dying in the winter, but ſome of it remaining alive, and putting forth freſh ſhoots in the ſpring. Leaves lanceolate (thoſe which appear firſt in the ſpring rather elliptical, as repreſented in Petiver's figure,) ſomewhat waved at the edge, even and ſhining on the upper ſurface, prickly at the edges and along the midrib on the under ſide, from three to ſix in a whorl, but moſtly five. Flowers in dichotomous terminating panicles of a dirty yellow, always five-cleft, five-ſtamened, and without any calyx. This latter circumſtance is common to it with Rubia tinctorum. R. peregrina ſeldom produces more than one perfect ſeed; perhaps there are not more than two or three inſtances on any one plant in which both ſeeds attain perfection. The plant in climbing up the rocks and through the ſhrubs ſupports itſelf by means of the prickles on the angles of the ſtem, and under the margins and midribs of the leaves [x].

Native of England, among buſhes and on rocks; near Biddeford in Devonſhire, and common in hedges through great part of the county; and on St. Vincent's rocks near Briſtol, by Ray: in Dorſetſhire, hedges in Purbeck, and between Whitchurch and Milbourne St. Andrew's; yet found under Hod-hill, in the pariſh of Stour-pain near Blandford, as mentioned by Parkinſon, where Dr. Pulteney ſays he has ſeen it many times green and flouriſhing in the month of january; found alſo in Portland, by A. B. Lambert, Eſq. [y]: in Cornwall, by F. Borone: near Exmouth in Devonſhire, by Dr. Withering; in the Iſle of Wight, by Dr. Stokes; in a wood oppoſite St. Vincent's rocks, by Mr. Swayne; on Tunbridge rocks, by the Rev. Dr. Goodenough; at Chepſtow in Monmouthſhire, by Dr. Smith.

4. This is an evergreen plant, reſembling the preceding, but the leaves are rugged with recurved prickles on the edge only, not on the keel. Flowers panicled, pale, mucronate, five-cleft.

Native of Majorca [z]. Introduced in 1762, by Mr. James Gordon. It flowers in july [a].

5. Leaves five or ſix in a whorl. Flowers yellowiſh, axillary, on three-flowered peduncles [b].

Native of the Canary iſlands. Introduced 1779, by Mr. Francis Maſſon. It flowers in ſeptember [c].

6. Stems diffuſed, very rugged, four-cornered. Leaves four or ſix in a whorl, linear-acute, the keel and margin ciliate with little prickles, and rugged along the rib of the upper ſurface. Flowers yellow, flat, five-cleft [d].

Native of Minorca. Introduced in 1772, by Monſ. Richard. It flowers in july and auguſt [e].

7. This is a diffuſed ſcandent plant, quite ſmooth. Stem four-cornered, rugged with recurved prickles at the corners, and branched. Leaves commonly four in a whorl, ſometimes but ſeldom ſix, ovate, cordate, acute, with the edge turned back, the whole rugged with muricate dots, eſpecially along the edge and keel, ſpreading, ſhorter than the internodes: petioles four-cornered, with recurved prickles. Flowers axillary, panicled, white. Panicle very ſpreading, in whorls and ſubtrichotomous. Peduncles and pedicels capillary, four-cornered. Bractes ſubulate-ſetaceous [f].

Native of the Cape of Good Hope, Siberia, China, Japan, where it is uſed in dying; in many parts of the Eaſt Indies and Africa.]

PROPAGATION AND CULTURE.

In all the Netherlands, there is no where better Madder cultivated, than in Schowen, one of the iſlands of Zealand, and the culture is performed in the following manner:

The land which is deſigned for Madder, if it is ſtrong and heavy, is ploughed twice in autumn, that the froſt in winter may mellow it and break the clods; then it is ploughed again in the ſpring, juſt before the time of planting the Madder; but if the ground is light, then it is ploughed twice in the ſpring; at the laſt ploughing it is divided into lands of three feet broad, with furrows between each land four or five inches deep. Madder requires a loamy ſubſtantial ſoil, not too ſtiff and heavy, nor over light and ſandy; for although it may thrive tolerably well in the latter, yet ſuch land cannot have a ſecond crop of Madder planted upon it in leſs than eight or ten years interval; but in Schowen, where the land is ſubſtantial, they need not ſtay longer than three or four years, in which interval the ground is ſown with Corn, or planted with any kinds of pulſe. It is granted, that the beſt land for producing Madder is in Schowen, where a gemet of land, which is three hundred ſquare rods of twelve feet each, will yield from one thouſand pounds to three thouſand pounds weight, according to the goodneſs of the land and the favourableneſs of the ſeaſons; but in light land, the quantity is from five hundred to a thouſand pounds weight.

The time for planting Madder begins towards the end of april, and continues all may, and ſometimes in very backward ſprings, there is ſome Madder planted the beginning of june. The young ſhoots from the ſides of the root are taken off from the mother plant, with as much root as poſſible; theſe are called kiemen, and are planted with an iron dibble in rows at one foot aſunder, and commonly four kiemen in a row.

The quantity of theſe ſlips (or kiemen) as is required to plant one gemet of land, are ſold at different prices, according to the price which Madder bears, or to the demand for the plants; they are often ſold from ſixteen to twenty guilders, and ſometimes they have been ſold for ten to eleven pounds Flemiſh, but the loweſt price is from fifteen guilders to three pounds Flemiſh.

The expenſe of planting out a gemet of land with ſlips (or kiemen) coſts for labour only, from ſixteen to twenty guilders, according as the land is heavy or light: there are generally employed ſix men to plant, two to rake the ground, theſe earn each a guilder a day; and five or ſix women or boys, called carpers or pluckers of the ſhoots or kiemen, theſe earn twelve Dutch pence a day, or two ſchillings.

The firſt year the Madder is planted, it is cuſtomary to plant Cabbages or Dwarf Kidney-beans, in the furrows between the beds, but there is always great care taken to keep the ground clear from weeds; this is generally contracted for at two pounds Flemiſh for each gemet of land.

In ſeptember or october, when the young Madder is cleaned for the laſt time that ſeaſon, the green haulm (or ſtalks) of the plants, is carefully ſpread down over the beds, without cutting any part off, and in november the Madder is covered over the haulm with three or four inches of earth.

This covering of the Madder, is performed either with the plough or with the ſpade; if it is done by the firſt, it coſts two guilders and a half, or three guilders in ſtrong land each gemet, and over and above this, one guilder and a half to level the tops of the beds, and make them ſmooth; but it is better performed with the ſpade, only it is more chargeable, for that coſts from eight to ten guilders each gemet, but at the ſame time the clods are broken, and the ſurface of the beds is made ſmooth and even.

The ſecond year in the beginning of april, which is about the time the kiemen or young ſhoots are beginning to come out, the earth on the top of the beds ſhould be ſtuffled over and raked to deſtroy the young weeds, and make the ſurface ſmooth and mellow, that the kiemen may ſhoot out the eaſier above ground; this labour coſts three ſhillings each gemet.

The ſecond ſummer there muſt be the ſame care taken to keep the Madder clean as in the firſt, and then nothing is planted in the furrows, or ſuffered to grow there; at the laſt time of cleaning the ground, in ſeptember or october, the green haulm is again ſpread down upon the beds; and in november the Madder is again covered with earth, in the ſame manner as the firſt year.

By this method of culture, one can ſee how neceſſary it is to plant the Madder in beds, for thereby it is much

much eaſier covered with the earth of the furrows; and hereby the earth of the beds is every time heightened, whereby the Madder roots will be greatly lengthened, and the kiemen or young ſhoots will have longer necks, and by being thus deeply earthed, will put out more fibres and have much better roots, without which they will not grow; and it is of equal uſe to the mother plants; for by this method the roots will be longer; and in this conſiſts the goodneſs and beauty of the Madder, for thoſe which have but few main roots, are not ſo much eſteemed as thoſe which are well furniſhed with ſide roots called tengels; a Madder plant that has many of theſe roots, is called a well bearded Madder plant; therefore one muſt never cut off theſe ſide roots, for by ſo doing there will be a leſs crop of Madder, and but few kiemen or young ſhoots can be produced; beſides, by the loſs of moiſture, ſometimes the plants will droop and become weak; and there is great profit in having a large quantity of kiemen to draw in the ſpring, which are in plenty the ſecond and third years.

The Madder roots are ſeldom dug up the ſecond year, but generally after it has grown three ſummers, therefore the culture of the third year is the ſame as in the ſecond, during the ſpring and ſummer.

Before the firſt day of ſeptember, it is forbidden to dig up any Madder in this iſland; but on that day early in the morning, a beginning is made, and the perſon who carries the firſt cart load to the ſtove, has a premium of a golden rider, or three ducats.

The digging up the Madder of a gemet of land, coſts from thirty-ſix to one hundred guilders, according to the goodneſs of the crop, and the lightneſs or ſtiffneſs of the ground, but in light land it coſts from nine to ten pounds Flemiſh; the perſons who are adroit in this buſineſs, are generally paid five ſhillings Flemiſh per day.

The Madder produces flowers in the middle of ſummer, and ſometimes a few ſeeds, but they never ripen here; nor would they be of uſe to cultivate the plants, ſince it is ſo eaſily done by the kiemen.

Some years paſt they began to plant here the great wild Madder, which was called French Madder, but this was not eſteemed ſo good for uſe as the tame Madder, from which it differs much, ſo that was not continued. The more bitter of taſte the roots of the Madder are, when taken out of the ground before it is brought to the ſtove, the leſs it will loſe of its weight in drying, and is the better afterward for uſe.

When the Madder is dug out of the ground, it is carried to the ſtove, and there laid in heaps; in that which is called the cold ſtove, and ſeparated with hurdles made of wicker, and memorandums kept of each parcel, and to what countryman it belongs, that each may be dried in their turns, and prepared or manufactured, for which turn generally lots are caſt beforehand. The Madder thus carried to the ſtove is relzyn.

This relzyn is carried about ſix o'clock in the morning, into the tower or ſteeple, hoiſted in baſkets by ropes to the rooms, and divided or ſpread, where it remains till the next day, two or three o'clock in the morning, about twenty or twenty-one hours; then thoſe roots which have lain in the hotteſt places are removed to cooler, and thoſe in the cooler are removed to the hotter places nearer the oven. This is continued for four or five days, according as there has been more or leſs carried there; but it is always the goods of one perſon, that every one may have his own, and of as equal quality as poſſible, when it is delivered out.

When the Madder is ſufficiently dried in the tower, then it is threſhed on the threſhing-floor, which is made clean from dirt or filth, and then it is brought to the kiln, and there ſpread on a hair-cloth for about twenty hours, during which time the kiln is made more or leſs hot, according as the roots are more or leſs thick, or the weather being more or leſs cold.

From the kiln the Madder is moved to the pounding-houſe, and is there pounded on an oaken block made hollow, with ſix ſtampers plated at the bottom with iron bands; theſe ſtampers are kept in motion by a mill very much reſembling a griſt-mill, which is turned by three horſes; the preſence of the pounding-maſter is here always required, to ſtir the Madder continually with a ſhovel, to bring it under the ſtampers. When the Madder is thus properly pounded, it is ſifted over a tub till there is enough to fill a caſk: this firſt pounding, which chiefly conſiſts of the thinneſt and ſmalleſt roots, and the outſide huſks with ſome earth, which by drying and threſhing could not be ſeparated, is called mor mull.

What remains in the ſieve is put on the block again, and pounded a ſecond time, and when the pounding-maſter gueſſes a third part is pounded, then the Madder is taken out again and ſifted over another tub, and put into a ſeparate caſk, and this is called gor gemeens; that which remains in this ſecond operation, not enough pounded in the ſieve, is for the third time put on the block, and pounded till it is all reduced to powder, which is called kor kraps.

When the Madder is cleanſed from the dirt and mull, and is entirely pounded at once, then it is called oor onberoofde, ſo that this onberoofde actually conſiſts of the gemeens and kraps pounded together, and ſifted without ſeparating them from each other.

When there is two thirds of kraps, and one third gemeens, which was ſeparately prepared or manufactured, then they are called two and one, or marked $\frac{1}{2}$.

The ſweepings of the ſtove, as alſo of the ground and beams being ſwept together is not loſt, but is put amongſt the mull, or ſold by itſelf.

The ſweepings of the mill, and every part of the pounding-place, is alſo gathered together, and put into a caſk; this is called den beer.

When the Madder is thus prepared and put into caſks, it is in Zealand examined by ſworn aſſayers and tried, if it is not faulty packed up; that is, whether in the preparing it is properly manufactured, or falſely packed up, and to ſee if every part of the caſk is filled with Madder of equal goodneſs and quality, not burned in the drying, or mixed with dirt; which the aſſayers by certain trials, and by weighing and waſhing of the Madder can know, if it is according to the ſtatutes of the country.

There are ſundry ſtatutes made and publiſhed by the ſtates of Zealand, concerning the preparing of Madder; as one of the 28th of july 1662, one on the 29th of ſeptember, and 31ſt of october 1671, another on the 23d of ſeptember 1699, and the laſt on the 28th of april 1735: by which ſtatutes, among other things, it is ſtrictly forbidden, That any perſon ſhall prepare kraps, in which there ſhall be more than two pounds of dirt in a hundred weight; nor above eight pounds in the like weight of onberoofde, or in gemeens more than twelve pounds in a hundred weight.

If the Madder upon trial is found good, the arms of the city or village, and the ſign of the ſtove where the Madder was prepared, is painted on the caſk with black paint. The trial of the Madder is in no place more exact, or more religiouſly obſerved, than in the city of Zirkzee; therefore the merchants in Germany, who know this, always prefer the Madder of that place to all others, and will not buy any which has not the arms of Zirkzee painted upon the caſks, if they are to be had.

We before mentioned the tower, the kiln, &c. where the Madder is dried and prepared for uſe.

The tower is the place where the Madder is firſt dried. This is heated by fifteen or ſixteen pipes or flues of brick-work, which run on each ſide under the floor, and are covered with low burnt tiles, ſome of which are looſe; ſo that by taking up theſe, the heat is moderated and conducted to any part of the tower, the perſon who has the care of drying the Madder pleaſes.

The tower has four or five lofts made of ſtrong laths; they are four or five feet above each other, upon which the Madder is laid; theſe are heated by an oven, which is placed in the room where the work people live, and is by them called the glory.

The kiln is in a room whoſe length is equal to the breadth

Digitized by Google

breadth of the ſtove, and is entirely arched over at the top; the oven by which the kiln is heated, is called the hog; this is built upon a ſtone wall, which riſes a foot or two above ground; and the ſmall arch by which the heat paſſes through every part, has ſeveral ſquare little holes in the brick-work, that the heat may come out; over theſe holes, on the top of the kiln, are laid wooden laths the whole length, and upon them a hair-cloth, on which the Madder is laid to dry, before it is carried to the pounding-place. In the Madder-ſtoves there is no other fuel uſed but Friezland turf, which gives an equal and moderate heat.

In the Madder-ſtoves, the people work more by night than day; firſt, becauſe at the time of the year when the Madder is brought into the ſtoves, the nights are much colder than the days; and ſecondly, that the maſter, who muſt be always attentive to his work, may not be interrupted by viſitors; and thirdly, becauſe they ſee leſs duſt; but principally, becauſe the Madder which is pounded in the night is of a much better colour than that which is pounded in the day.

In the Madder-ſtoves are always conſtant workmen, one who is the drier, who has the care of drying the Madder in the tower and the kiln; for the right performance of this, art and experience are required, the goodneſs of the Madder greatly depending on the right drying. This perſon is a ſort of foreman, and has the direction of all the workmen; his pay is five ſtivers, for every hundred weight of Madder which is prepared in the ſtove; he has one perſon under him for his aſſiſtant, to perform part of the laborious work, and to be always at hand; this man is paid eighteen or nineteen ſhillings per week Flemiſh, which is the conſtant wages.

The third perſon is the pounder, who is always preſent when the Madder is pounding, and with a particular ſhovel which is ſmall, and fitted to the cavity of the pounding-block, ſtirs the Madder from time to time, to bring it under the ſtampers; he is paid four ſtivers for every hundred weight of Madder.

The fourth is a driver, who with a team of three horſes, cauſes the mill to turn and pound the Madder; his pay for himſelf and the three horſes, from eight to nine ſtivers per hundred weight, according as he can bargain.

Beſides theſe four, there are five other aſſiſtants, who lay the Madder on and take it off; this is often performed by the wives and boys of the other workmen; theſe five have fifty ſtivers for every three thouſand pounds of Madder, which is prepared, ſo they have each ten ſtivers.

There are nineteen or twenty Madder-ſtoves in the iſland of Schowen, which, at an average, prepare in one crop, that laſts from ſeptember to february, ten thouſand weight of Madder each, which in the whole, amounts to two million pounds weight; and if we ſuppoſe, that the Madder is ſold at an average for four pounds Flemiſh per hundred weight, which is a moderate price, one may ſoon reckon what advantage the culture of this dyeing commodity produces to this one iſland.

The countrymen pay to the owners of the Madder-ſtoves, two guilders for preparing every hundred weight of mull, and for each hundred weight of hard Madder; that is, of kraps, gemeens, or onberoofde, three guilders, according as they will have them prepared.

The building of a Madder-ſtove quite new from the foundation, coſts in the whole about twenty-four hundred pounds Flemiſh, which is twelve hundred pounds ſterling.

The above is the method of cultivating Madder in Zealand, where the beſt Madder is now produced; to this I ſhall add, what I have obſerved of the growing of Madder in other parts of Holland, as alſo the experience I have had of the growth of Madder in England, with an account of the method of planting it here.

In the year 1727, I obſerved a great quantity of this plant cultivated in Holland, between Helvoetſluys and the Brill; and it being the firſt time I had ever ſeen any conſiderable parcel of it, I was tempted to make ſome enquiries about its culture, and take ſome minutes of it down upon the ſpot, which I ſhall here inſert, for the uſe of ſuch as may have curioſity to attempt the culture of it.

In autumn they plough the land, where they intend to plant Madder in the ſpring, and lay it in high ridges, that the froſt may mellow it: in march they plough it again, and at this ſeaſon they work it very deep, laying it up in ridges eighteen inches aſunder, and about a foot high; then about the beginning of april, when the Madder will begin to ſhoot out of the ground, they open the earth about their old roots, and take off all the ſide-ſhoots which extend themſelves horizontally, juſt under the ſurface of the ground, preſerving as much root to them as poſſible; theſe they tranſplant immediately upon the tops of the new ridges, at about a foot apart, obſerving always to do this when there are ſome ſhowers, becauſe then the plants will take root in a few days, and will require no water.

When the plants are growing, they carefully keep the ground hoed, to prevent the weeds from coming up between them; for if they are ſmothered by weeds, eſpecially when young, it will either deſtroy or weaken them ſo much, that they ſeldom do well after. In theſe ridges they let the plants remain two ſeaſons, during which time they keep the ground very clean; and at Michaelmas, when the tops of the plants are decayed, they take up the roots and dry them for ſale. This is what I could learn of their method of cultivating this plant, to which I will ſubjoin a few obſervations of my own, which I have ſince made upon the culture of Madder in England.

The land upon which I have found Madder thrive beſt, is a ſoft ſandy loam, and if it has been in tillage ſome years, it will be better than that which is freſh broken up. This ſhould have at leaſt a depth of two feet and a half, or three feet of good earth, and muſt be quite clear from Couch, or the roots of any bad weeds; for as the roots of Madder ſhould remain three years in the ground, ſo where there are any of thoſe weeds which ſpread and multiply at their roots, they will intermix with the Madder roots, and in three years will have taken ſuch poſſeſſion of the ground, as to greatly weaken the Madder, and render it very troubleſome to ſeparate when the Madder is taken up.

The ground ſhould be ploughed deep before winter, and laid in ridges to mellow; and if it is not too ſtrong, there will be no neceſſity for ploughing it again, till juſt before the time of planting the Madder, when the land ſhould be ploughed as deep as the beam of the plough will admit; and there ſhould be men following the plough in the furrows, which ſhould dig a full ſpit below the furrow, and turn it up on the top; by preparing the ground of this depth, the roots of the Madder will ſtrike down, and be of greater length, in which the goodneſs of the crop chiefly conſiſts. The land being thus prepared and made level, will be fit to receive the plants. The beſt time for planting Madder is about the middle or end of april, according as the ſeaſon is more or leſs forward, which muſt be determined by the young ſhoots; for when theſe are about two inches above ground, they are in the beſt ſtate for planting.

In the taking up of theſe ſhoots for planting, the ground ſhould be opened with a ſpade, that they may be ſeparated from the mother plants with as much root as poſſible; for if the roots are broken off, they will not ſucceed: theſe plants ſhould be drawn up no faſter than they are planted; for if they lie long above ground, they will ſhrink and their tops will wither, and then they often miſcarry; therefore if they are brought from a diſtant place, there ſhould be great care taken in the packing of them up for carriage; eſpecial regard ſhould be had not to pack them ſo cloſe, or in ſo great quantity, as to cauſe them to heat, for that will ſoon ſpoil them; but if they are a little withered by lying out of the ground, their roots ſhould be ſet upright in water for a few hours, which will ſtiffen and recover them again.

In the planting of Madder, there are ſome who make

Digitized by Google

make the rows but one foot aſunder, others one foot and a half, ſome two feet, and others who allow them three feet diſtance; I have made trial of the three laſt diſtances, and have found when the roots have been left three years in the ground, that three feet diſtance row from row is the beſt; but if it is taken up in two years, two feet aſunder may do very well; and the diſtance in the rows, plant from plant, ſhould be one foot, or a foot and a half.

If there is no danger of the ground being too wet in winter, the plants may be planted on the level ground; but if on the contrary, the ground ſhould be raiſed in ridges where each row of plants is to be ſet, that their roots may not reach the water in winter, for if they do, it will ſtop their downright growth; and this is the reaſon why the Dutch, who plant Madder in the Low Countries, raiſe their ridges ſo high as two or three feet; and in Zealand, where the ground is drier, they raiſe the beds four or five inches above the intervals, that the wet may drain off from the beds where the Madder is planted.

The method of planting is as follows: the ground being made ſmooth, a line is drawn acroſs it to mark out the rows, that they may be ſtraight, for the more convenient cleaning, and for the better digging or ploughing the ground between the rows; then with an iron-ſhod dibble, holes are made, at the diſtance which the plants are to ſtand from each other. The depth of the holes muſt be in proportion to the length of the roots of the plants, which muſt be planted the ſame depth they had been while they were upon the mother plants; for if any part of the root is left above ground, the ſun and winds will dry it, which will retard the growth of the plant; and ſhould any part of the green be buried in the ground, it will not be ſo well; though of the two, the latter will be leſs prejudicial, eſpecially if there is not too much of the green buried. When the plants are put into the holes, the earth ſhould be preſſed cloſe to them to ſecure them from being drawn out of the ground, for crows and rooks frequently draw the new plants out of the ground before they get new roots, where there is not this care taken: ſo that in two or three days, I have known half the plants on a large piece of land deſtroyed by theſe birds.

If there happen to be ſome ſhowers of rain fall in a day or two after the plants are planted, it will be of great ſervice to them, for they will preſently put out new roots, and become ſtrong; ſo that if dry weather ſhould afterwards happen, they will not be in ſo much danger of ſuffering thereby, as thoſe which are later planted. There are ſome who, from a covetous temper of making moſt uſe of the ground, plant a row of Dwarf Peas or Kidney Beans between the rows of Madder, and pretend that thereby the land is kept cleaner from weeds; but I am very certain the crop of Madder is injured thereby much more than the value of thoſe things which grow between the rows, as I have experienced; therefore I adviſe thoſe perſons who plant Madder, never to ſow or plant any thing between the rows, but to keep the Madder quite clean from weeds, or any other kind of vegetable.

In order to keep the ground thus clean, it ſhould be ſcuffled over with a Dutch hoe, as ſoon as the young weeds appear. When a man can perform a great deal of this work in a day, and if it is done in dry weather, the weeds will dry as faſt as they are cut down; whereas, when the weeds are left to grow in the ſpring, ſo as to get ſtrength, they are not ſo ſoon deſtroyed, and the expenſe of hoeing the ground then will be more than double; beſides, there will be danger of cutting down ſome of the weaker plants with the weeds, if the perſons employed to perform this work are not very careful; therefore it is much cheaper, as alſo better for the Madder, to begin this work early in the ſpring, and to repeat it as often as the weeds render it neceſſary; for by keeping the ground thus conſtantly clean, the Madder will thrive the better.

During the firſt ſummer, the only culture which the Madder requires, is that of keeping it clean in the manner before directed; and when the ſhoots or haulm of the plants decay in autumn, it ſhould be raked off the ground; then the intervals between the rows ſhould be either dug with a ſpade or ploughed with a hoeing plough, laying up the earth over the heads of the plants in a roundiſh ridge, which will be of great ſervice to the roots. The Dutch cover the haulm of their Madder with earth, leaving it to rot upon the ground; this perhaps may be neceſſary in their country to keep the froſt out of the ground; but as I have never found that the ſevereſt winters in England have injured the Madder roots, there is not the ſame neceſſity for that practice here.

The following ſpring, before the Madder begins to ſhoot, the ground ſhould be hoed and raked over ſmooth, that the young ſhoots may have no obſtruction; and if there ſhould be any young weeds appearing on the ground, it ſhould be firſt ſcuffled over to deſtroy the weeds, and then raked over ſmooth; after this, the ſame care muſt be taken in the following ſummer to keep the ground clean; and if it is performed by the hoe plough, the earth of the intervals ſhould be thrown up againſt the ſide of the ridges, which will earth up the roots, and greatly increaſe their ſtrength; but before the ground of one interval is ſo hoed, the haulm of the plants ſhould be turned over to the next adjoining interval; and if they are permitted ſo to lie for a fortnight or three weeks, and then turned back again on thoſe intervals which were hoed, obſerving firſt to ſcuffle the ground to deſtroy any young weeds which may have appeared ſince the ſtirring of the ground; then the alternate intervals ſhould be ploughed in like manner, turning the earth up againſt the oppoſite ſides of the roots: by this method the intervals will be alternately ploughed, and the plants earthed up, whereby the ground will be kept clean, and ſtirred, which will greatly promote the growth of the roots; and by this method the ſuperficial ſhoots will be ſubdued, and the principal roots greatly ſtrengthened. The following autumn the ground ſhould be cleared of the haulm and weeds, and the earth raiſed in ridges over the roots, as in the foregoing year.

The third ſpring the roots will furniſh a great ſupply of young plants; but before theſe appear, the ground ſhould be cleared and raked ſmooth, that the ſhoots may have no obſtruction to their coming up; and when the young plants are fit to take off, it ſhould be performed with care, always taking off thoſe which are produced at the greateſt diſtance from the crown of the other plants, becauſe thoſe are what rob them moſt of their nouriſhment, and the wounds made by ſeparating them from the old roots are not near ſo hurtful as thoſe near the crown; for the ſtripping off too many of the ſhoots there will retard the growth of the plants.

The culture of the Madder in the third ſummer muſt be the ſame as the ſecond; but as the roots will then be much ſtronger, the earth ſhould be laid up a little higher to them at the times when the ground is cleaned; and if all the diſtant ſuperficial ſhoots, which come up in the intervals are hoed or ploughed off, it will be of ſervice to ſtrengthen the larger downright root; and as the haulm will now be very ſtrong and thick, the frequent turning it over from one interval to another will prevent its rotting; for if it lies long in the ſame poſition, the ſhoots which are near the ground, where there will be always more or leſs damp, and being covered with the upper ſhoots, the air will be excluded from them, which will cauſe them to rot, for the ſhoots of Madder are naturally diſpoſed to climb up any neighbouring ſupport; and in places where they have been ſupported, I have ſeen them more than ten feet high; but the expenſe of ſtaking the plants to ſupport their ſhoots would be much too great to be practiſed in general; therefore the other method of turning the haulm over from one interval to the other will be found of great uſe, for hereby it is kept from decaying, and by ſo doing the ſun is alternately admitted to each ſide of the roots, which is of more conſequence to the growth of the Madder than moſt people conceive; and from many repeated

Digitized by Google

trials I have found, that where the haulm has decayed or rotted in ſummer, it has greatly retarded the growth of the roots. There have been ſome ignorant pretenders who have adviſed the cutting off the haulm in ſummer, in order to ſtrengthen the roots; but whoever practiſes this, will find to their coſt the abſurdity of this method; for I have fully tried this many years ago, and have always found that every other root, upon which this was practiſed, was at leaſt a third part ſmaller than the intermediate roots, whoſe haulm was left entire. The firſt occaſion of my making this experiment was, becauſe the plants had been ſet too near each other, and the ſeaſon proving moiſt had increaſed the number and ſtrength of the ſhoots, ſo that they were ſo thick, as that many of them began to rot; to prevent which, I cut off the ſhoots of every other plant to give room for ſpreading the others thinner, but ſoon after this was done, the plants produced a greater number of ſhoots than before, but they were weaker, and the effect it had upon the roots was as before related; ſince which time I have frequently repeated the experiment on a few roots, and have always found the effect the ſame.

As ſoon as the haulm of the Madder begins to decay in autumn, the roots may be taken up for uſe, becauſe then the roots have done growing for that ſeaſon, and will then be plumper and leſs liable to ſhrink than if they are dug up at another ſeaſon; for I have always found, that roots of every kind of plant, which are taken out of the ground during the time of their growing, are very apt to ſhrink, and loſe more than half their weight in a ſhort time; whereas, when they are taken up ſoon after their leaves decay, they will not ſoon after ſhrink much.

When the ſeaſon for digging up the Madder root is come, it ſhould be done in the following manner, viz. a deep trench ſhould be dug out at one ſide of the ground next to the firſt row of Madder to make a ſufficient opening to receive the earth, which muſt be laid therein in digging up the row of roots, ſo that it ſhould be at leaſt two feet broad, and two ſpits and two ſhovellings deep, and ſhould be made as cloſe as poſſible to the roots, being careful not to break or cut the roots in doing it; then the row of roots muſt be carefully dug up, turning the earth into the trench before-mentioned. In the doing of this there ſhould be to every perſon who digs, two or three perſons to take out the roots, that none may be loſt, and as much of the earth ſhould be ſhaken out of the roots as poſſible; and after the principal roots are taken up, there will be many of the long fibres remaining below; therefore, in order to get the roots as clean as poſſible, the whole ſpot of ground ſhould be dug of the ſame depth as the firſt trench, and the pickers muſt follow the diggers to get them all out to the bottom. As the digging of the land to this depth is neceſſary, in order to take up the roots with as little loſs as poſſible, it is a fine preparation for any ſucceeding crop; and I have always found that the ground where Madder has grown, produced better crops of all kinds than land of equal goodneſs, which had not the like culture.

After the roots are taken up, the ſooner they are carried to the place of drying, the finer will be their colour; for if they lie in heaps, they are apt to heat, which will diſcolour them; or if rain ſhould happen to wet them much, it will have the ſame effect, therefore no more roots ſhould be taken up than can be carried under ſhelter the ſame day.

The firſt place, in which the roots ſhould be laid to dry, muſt be open on the ſides to admit the air, but covered on the top to keep out the wet. If a building is to be erected new, ſuch as the tanners have for drying their ſkins will be as proper as any, for theſe have weather-boards from top to bottom at equal diſtances to keep out the driving rain, but the ſpaces between being open admit the air freely; and if, inſtead of plank floors or ſtages above each other, they are laid with hurdles or baſket-work, upon which the roots are laid to dry, the air will have freer paſſage to the under ſide of the roots, which will dry them more equally.

In this place they may remain four or five days, by which time the earth which adhered to the roots will be ſo dry as to eaſily rub off, which ſhould be done before the roots are removed to the cold ſtove, for the ſlower the roots are dried, the leſs they will ſhrink, and the better will be the colour of the Madder; and the cleaner the roots are from earth, the better the commodity will be for uſe when prepared.

After the roots have laid a ſufficient time in this place, they ſhould be removed into another building called the cold ſtove, in which there ſhould be conveniencies of flues paſſing through different parts of the floor and the ſide-walls; in this the roots ſhould be laid thin upon the floors, and turned from time to time as they dry, taking thoſe roots away, which are neareſt to the flues which convey the greateſt heat, placing them in a cooler part of the room, and removing ſuch of them as had been in that ſituation to the warmer, from whence the others are taken. The conſtant care in this particular will be of great ſervice to the quality of the Madder; for when this is properly conducted, the roots will be more equally dried, and the commodity, when manufactured, will be much fairer and better for uſe.

When the outſide of the roots has been ſufficiently dried in this cold ſtove, they ſhould be removed to the threſhing floor, which may be the ſame as in a common barn where Corn is threſhed. The floor of this ſhould be ſwept, and made as clean as poſſible; then the roots ſhould be threſhed to beat off their ſkins or outſide coverings; this is the part which is prepared ſeparately from the inner part of the root, and is called mull, which is ſold at a very low price, being the worſt ſort of Madder, ſo cannot be uſed where the permanency or beauty of the colours is regarded; theſe huſks are ſeparated from the roots, and pounded by themſelves, which are afterwards packed up in ſeparate caſks, and ſold by the title of mull. If this is well prepared, and not mixed with dirt, it may be ſold for about fifteen ſhillings per hundred weight, at the price which Madder now bears; and this, as is ſuppoſed, will defray the whole expenſe of drying the crop.

After the mull is ſeparated from the roots, they muſt be removed to the warmer ſtove, where they muſt be dried with care; for if the heat is too great, the roots will dry too faſt, whereby they will loſe much in weight, and the colour of the Madder will not be near ſo bright; to avoid which, the roots ſhould be frequently turned, while they remain in this ſtove, and the fires muſt be properly regulated. If ſome trials are made by fixing a good thermometer in the room, the neceſſary heat may be better aſcertained than can be done any other way; but this will require to be greater at ſome times than at others, according as the roots are more or leſs ſucculent, or the weather more or leſs cold or damp; but it will always be better to have the heat rather leſs than over much; for, though the roots may require a longer time to dry with a ſlow heat, yet the colour will be better.

When the roots are properly dried in this ſtove, they muſt be carried to the pounding-houſe, where they muſt be reduced to powder in the manner before related; but whether it is neceſſary to ſeparate the kraps from the gemeens, as is now practiſed by the Dutch, the conſumers of Madder will be better judges than myſelf.

There have been ſome objections of late mentioned to the introducing, or rather retrieving the culture of Madder in England, which it may be proper here to take notice of, leſt they ſhould have ſo much weight as to prevent many perſons from engaging in it. The firſt which has been generally ſtarted is, that the land in this country is not ſo well adapted for growing Madder as that in Holland: to which I can with truth affirm, that there are vaſt tracts of land here much better adapted for producing Madder than the beſt land in Zealand; and from the experience which I have had of its growth, will produce a greater crop.

Another objection which I have heard, was the labour in Holland being cheaper than in England. The Dutch will always underſell us, ſo conſequently will

Digitized by Google

maintain this branch of trade; but this is certainly a great miſtake: for though the labourers employed in cultivating Madder may not earn ſo great wages as is generally paid in England, ſure I am, that the difference between an expert Engliſh labourer and that of the beſt Dutchman, in the ploughing, hoeing, planting, &c. of Madder, is much greater than that of their pay; for I am ſure a good Engliſh gardener or ploughman will do more buſineſs, and perform it better, in four days, than the beſt workman in Holland can do in ſix. What I now ſay is greatly within compaſs, from my own knowledge; ſo that, ſuppoſing we were to proceed in the ſame manner now practiſed by the Dutch, this could be no objection to the cultivating of Madder; but we ſhould ſoon find ways of performing the moſt laborious part, at much leſs expenſe, by means of the hoeing plough, which may be uſed to great advantage in the cultivation of Madder, whereby the expence will be much leſſened; and, when once this is well eſtabliſhed in England, there can be no doubt but that great improvements will be made both in the culture and method of preparing the commodity for uſe.

There have been objections made againſt farther trials of growing Madder, becauſe ſome who have engaged in it have not ſucceded: but in anſwer to this, it muſt be obſerved, that their ill ſucceſs was owing to a want of ſkill. Some of them continued to plant repeated crops of Madder on the ſame ſpot of ground, till the roots became ſo ſmall, as ſcarce to pay the expenſe of digging up; and here it is proper to obſerve, that Madder ſhould not be planted on the ſame land, till after an interval of ſeven or eight years; during which interval the ground may be ſown with any ſort of grain, or kitchen vegetables, which it will produce to great advantage after Madder, becauſe the land will be wrought ſo deep. The Dutch always ſow grain upon their Madder ground in the intervals of four years, and have great crops from it; and they are obliged, from the ſcarcity of land fit for this purpoſe, to plant the ſame ground after an interval of four years; but, as we are not under the ſame neceſſity, it will be much better to ſtay eight years, for the roots of Madder are very ſimilar to thoſe of Aſparagus, and draw much the ſame nouriſhment from the ground; and it is well known that, when Aſparagus roots are dug up, which have been growing three years, if the ſame is planted with Aſparagus again in a few years, it will not thrive equal to that which is planted on ground upon which Aſparagus has not grown for ſeveral years; and this is always found to be the caſe even in kitchen-gardens near London, where, by the well working and frequent dunging the ground, it may be ſuppoſed changed in three or four years, more than the fields can poſſibly be in eight or ten.

Madder ſhould not be planted in very rich dunged land, for in ſuch there will be very large haulm, but the roots will not be in proportion; and, where there is much dung or ſea-coal aſhes, the Madder roots will be of a darker colour, as it will alſo where it is cultivated in the ſmoke of London, which is likewiſe the caſe with Liquorice; for that which grows in a ſandy loam at a diſtance from London, is always much brighter and clearer than that which grows in the rich lands in the neighbourhood of London.

In Zealand the Madder is principally cultivated by the kitchen-gardeners, who, in the change of their crops, do every fourth or fifth year plant the Madder upon the ſame ground again, in like manner as the gardeners in the neighbourhood of London plant Aſparagus for forcing in winter upon hot-beds. And as they have public kilns in Holland for drying of the Madder roots, ſo they know the expenſe of manufacturing the commodity for ſale, which renders the cultivation ſure and eaſy to them.

If the cultivation of Madder is carried on properly in England, it will employ a great number of hands from the time harveſt is over, till the ſpring of the year, which is generally a dead time for labourers, and hereby the pariſhes may be eaſed of the poor's rate, which is a conſideration worthy of public attention.

[Mr. Arbuthnot has ſhown by repeated experiments on Madder, that it may be cultivated profitably on ſoils not of extraordinary natural fertility: that good huſbandry, with rich manuring will be ſufficient to enſure a crop; conſequently that the Madder culture may be extended over moſt parts of the kingdom, except on poor, ſtoney or clayey ſoils: that the profit made by an application of the land during three years, is ſuperior to that of four: that the crop requires the ground to be well cleaned, on account of the great difficulty of extracting root-weeds from among the fibres of the plants, which conſequently would, in three years, get entire poſſeſſion of the ground: that the average profit of an acre amounts to above ſeven guineas, under the diſadvantages of firſt attempts and want of experience; if the ſoil had been naturally rich, ſuch as old Hop-grounds for inſtance, the profit would have been probably double: that the culture of this plant ameliorates and cleans the ſoil in a great degree, by the hand-hoeing, numerous horſe-hoeings, and extraordinary tillage the ground receives in taking up the roots: that rich manuring is of the greateſt importance: that great miſchief is done to the crops by drawing plants from them: that the roots bear exact proportion to the luxuriance of the branches and leaves.

Inſtead of ſpoiling the plantations of Madder by drawing; it is much better to leave ſuch a part of the crop, as will be wanting for a ſupply; taking up the plants for this purpoſe in the ſpring inſtead of the autumn. One acre of good Madder will yield plants enough for ten acres.

Old lay or new land is improper for this crop, on account of the wire-worm or ſod-worm: ſuch land ſhould be thrown into one round of crops before the Madder is planted.

The beſt manure is farm-yard dung. Top-dreſſings of all ſorts are too ſmall in quantity, however rich, to laſt with effect three years.

The land ſhould be ploughed about fourteen inches deep; the intervals between the rows repeatedly horſe-hoed with a ſhim, and then the plants earthed up by a double mould-board plough with expanding earth-boards: the rows alſo muſt be hand-hoed, as often as it is neceſſary.

The ſets may be planted in rows at eighteen inches or two feet diſtance, and a foot aſunder in the rows. The beſt diſtance will vary according to the goodneſs of the land. But in general the nearer the rows, the greater will be the crop; at leaſt as near as two feet equally diſtant. Single rows at four feet are not half ſo advantageous. Two rows on four feet are almoſt twice as beneficial as ſingle ones; but though two rows on a four-foot land amount in the whole to the ſame as equally diſtant at two feet, yet do they not near equal them in product; from which it ſhould ſeem that the plants ſhould be ſpread pretty equally over the land [c].

DESCRIPTIONS, *&c.*

[1. Stem round, pubeſcent; prickles yelloviſh, recurved at the end. Leaflets commonly five, ſubſeſſile, ovate, acute, doubly ſerrate, ſomewhat hairy; the end one very large, elongated, petioled. Common petiole channelled, hairy, with ſmall hooked prickles. Stipules in pairs, linear, acute, very narrow. Peduncles ſolitary, oppoſite to the leaf, an inch long, ſpreading, hairy, one-flowered, without any bractes. Calyx deeply five-cleft: ſegments ovate, very much drawn out at the point, entire, pubeſcent on both ſides. Petals a little ſhorter than the calyx, roundiſh, clawed, ſeeming to be white. Filaments ſhorter by half than the petals. Fruit globular, compoſed of very numerous ſmooth acini, and ſeeming not to be very ſucculent.—Found in the iſland of Mauritius by Commerſon; and communicated by Thouin[h].

2. Branches villoſe, green, beſet with hooked prickles. Leaves ovate-lanceolate, wrinkled and veined, ſharply double-ſerrate. Raceme ſimple. Peduncles villoſe, very prickly. Calyxes villoſe, longer than the petals. It ſeems to be allied to the next ſpecies; but the flowers are hermaphrodite, and the raceme terminating.—Its native place is unknown[i].

3. Native of New Zealand[k].

4. Stems ſuffruticoſe, biennial, upright, round, aculeate-hiſpid, or thick ſet with ſmall prickles, two feet high: they produce fruit the ſecond year, after which they lie down. Leaflets rhomb-ovate, acute, marked with lines, unequally ſerrate, white underneath. Petioles pubeſcent, prickly. Peduncles hiſpid. Flowers in panicles. Calyx tomentoſe, acuminate. Petals ſmall, white, blunt, flat. Fruit red, grateful to the ſmell and taſte, deciduous, briſtly with the permanent ſtyles[l], placed upon a conical receptacle.

The Raſpberry, was anciently called Raſpis or Raſpis-berry, and in ſome countries Hind-berry; alſo Framboiſe, from the French.

Native of many parts of Europe in rocky mountains, moiſt ſituations, woods and hedges. With us it is plentiful in Wales, and ſome parts of Scotland. Mr. Curtis remarked it in Graſs-wood, near Kilnſay, Yorkſhire; Mr. Hutchinſon, near Biſhop's Aukland; Dr. Withering, about Edgbaſton-pool, and near Birmingham; Mr. Crowe and Dr. Smith, between Norwich and Thorpe; Mr. Woodward, near Berkhamſtead in Hertfordſhire; Dr. Sibthorp, at Stokenchurch and Mongewell, in Oxfordſhire; Profeſſor John Martyn, in the Peak of Derbyſhire; Dr. Deering, between

[h] Smith. [i] Willdenow. [k] Forſter. [l] Smith.

Brockſtow

Digitized by Google

Brockſtow and Nuttal, in Nottinghamſhire; by Gerarde, near Harwood not far from Blackburne in Lancaſhire, and near Wiſterſom, where he went to ſchool, two miles from Nantwich in Cheſhire.

The Raſpberry flowers in may and june.

The fruit is grateful to moſt palates; as nature preſents it, but ſugar improves the flavour; accordingly it is much eſteemed when made into a ſweetmeat. The ripe fruit is fragrant, ſubacid and cooling, allays heat and thirſt, and promotes the natural excretions, in common with other ſummer fruits. A grateful ſyrup, prepared from the juice, is directed for officinal uſe, by the London Pharmacopœia. It diſſolves the tartar of the teeth; but for this purpoſe it is inferior to the Strawberry. The freſh leaves are the favourite food of kids [m].]

The varieties of the Raſpberry are, 1. The Red-fruited. 2. The White-fruited. 3. The twice-bearing; of which the firſt crop ripens in july, and the ſecond in october: thoſe of the latter ſeaſon having ſeldom much flavour. [The ſize of the fruit has alſo been much increaſed by culture, but perhaps at the expenſe of the flavour. Theſe are all accidental varieties, by the confeſſion of Mr. Miller himſelf;] but the Smooth Raſpberry he believes to be a diſtinct ſpecies; the leaves being trifoliate, larger than thoſe of the common ſort, woolly on their under ſide, the branches and ſtalks having no thorns. It produces few and ſmall fruit, which has occaſioned its being neglected.

5. The Virginian Raſpberry riſes with purpliſh ſtalks, a little higher than the common ſort. The leaves are of a lucid green on their upper ſide, but hoary on their under; their foot-ſtalks are taper; the fruit is of a deep black when ripe, has little flavour, and ripens late in autumn.

[Stem round, even, with recurved prickles, and covered with a bloom like a Plum. The petioles have alſo recurved prickles. Leaves ternate, with the middle leaflet pedicelled, ovate, gaſh-ſerrate, white-tomentoſe underneath. Raceme terminating. Fruit black. It varies alſo with a red fruit, more acid and pleaſant than our European Raſpberry. It differs chiefly from that, which it otherwiſe very much reſembles, in the leaves being commonly ternate, although the lateral leaflets often become two; the lateral leaflets being uſually angular; the prickles alternate, recurved, not ſcattered and in cluſters; the petioles alſo being prickly: but it is known at firſt ſight by the blue cloud or bloom on the ſtem [n].

Native of North America. It was cultivated in the botanic garden at Chelſea in 1696; and flowers in may and june [o].

6. Stem ſuffruticoſe, ſmooth, prickly. Branches weak, from flexuoſe-upright. Leaflets obovate, ſomewhat angular, with large teeth ending in a ſort of briſtle, ſmooth above, white-tomentoſe underneath. Flowers at the ends of the branchlets, in a ſort of panicle. Calyxes tomentoſe, hiſpid.

Native of Japan [p].

7. Branches ſmooth ſtriated beſet with ſcattered hooked prickles. Leaflets ſoft; the lateral leaflets obovate acute, unequally and groſsly toothed, the outer ſide ſublobate; the end leaflet obovate acute quite entire at the baſe. There are ſmall prickles on the petioles, the rib of the leaves, and the peduncles. Flowers white, in panicles at the end of the branches. Leaflets of the calyx tomentoſe, bent back. Petals obovate, twice as long as the calyx. It is very different from the common Bramble; nor does it agree with *R. occidentalis*, under which name it was ſent:—Native of Germany and Switzerland [q].

8. The ſtems have long procumbent woody ſhoots like thoſe of the Vine; theſe together with the petioles have ſtiff briſtles ſcattered over them. Leaflets gaſh-ſerrate, the middle one petioled. The peduncles alſo are hiſpid.

Native of Canada [r]. Cultivated by Mr. Miller in 1759. It flowers in auguſt.

9. Stems ſhrubby round tomentoſe, with abundance of reflex prickles. Leaves white underneath, veined. Calyxes tomentoſe, formed into a raceme.—Native of the Eaſt Indies [s].

Stems long, ſcandent, with many branches, and a few longiſh recurved prickles. Leaves roundiſh, ſerrate-gaſhed. Flowers purple, in a looſe terminating panicle. Berry roundiſh, red [t].—Native of the Eaſt Indies, China and Cochinchina.

10. Native of Paleſtine, Candia, &c.

11. This differs from *R. parviflius* in having the ſtem not hoary, but when young ſlightly pubeſcent only. Stem as in *R. fruticoſus*. Leaves ſmooth above, white underneath, gaſh-ſerrate [u].

It differs from the common Bramble (R. fruticoſus) in having the leaves gaſh-ſerrate, with the ribs prickly; the panicles terminating, diffuſed; the flowers and berries ſmall [x].—Native of Jamaica and the neighbouring iſlands.]

12. The Dewberry has weaker trailing ſtalks than the common Bramble. The leaflets are larger. The fruit is ſmaller, with few larger acini, and is of a deeper black colour.

[Stems proſtrate, round, rooting, pale green with a vivid glaucous tinge: though woody, they are only annual, or at moſt biennial. Leaflets gaſhed and ſerrate, downy (not hoary) beneath: the lateral leaflets ſeſſile, generally lobed on the outſide, of various forms. Stipules lanceolate. Petioles downy, prickly, obſcurely channelled above. Flowers few together, in terminating, downy, ſomewhat prickly panicles. Calyx ſilky, with long points, ſpreading. Petals waved and crumpled, white, rarely reddiſh. Fruit black with a bright blue tinge or bloom, compoſed of few large grains. Its flavour is agreeably acid, without the faint taſte of the common Blackberry.

Native of Europe, in dry ſhady ditches, woods and the borders of fields; flowering in june and july, and fruiting through auguſt and ſeptember, till froſts come on [y].

13. Stems biennial, roundiſh, red, not truly ſhrubby and perennial, much more brittle than the *fruticoſus*, ſo that it is rejected by thatchers, who uſe the other for binding their thatch; all the prickles are nearly ſtraight and not hooked. Leaves quinate or ternate: leaflets large, ſometimes exactly reſembling the leaves of a Hazel, unequally ſerrate and gaſhed; bright green above and ſmoothiſh, hairy but never hoary beneath; when the leaves are ternate, they are lobed on the outſide. Stipules, ſome ſetaceous others lanceolate. Petioles hairy, prickly. Panicle many-flowered. Calyx villoſe, ſpreading, in fruiting-time reflexed. Corolla white, earlier and larger than in the common Bramble. Fruit earlier, of a browner black, more gratefully acid than in the *fruticoſus*, and compoſed of rather fewer *acini* or grains [z].

Dillenius had remarked that there are two ſpecies of Bramble in our hedges, this with white, larger and earlier flowers, and another (fruticoſus) with reddiſh, ſmaller and later flowers. This difference has been ſince obſerved in Norfolk; and Mr. Woodward, who has marked the diſtinctions between them, ſuſpected this to be a variety of the *cæſius*; its larger ſize being owing only to its growing in open hedges, for in ditches it frequently throws out runners, which creep on the ground, and are not bigger than in the *cæſius*. Mr. Woodward's deſcription is given by Dr. Withering, who conſiders it as a variety of the *fruticoſus*. Dr. Smith has deſcribed and figured it as a diſtinct ſpecies, by the perſuaſion of Mr. Crowe, who has examined it carefully, and fully aſcertained it.

Profeſſor Hoffmann thinks that our *corylifolius* is the *fruticoſus* of his German Flora for 1800; and that the true *fruticoſus* is his *tomentoſus*. But the true *tomentoſus* (n. 7.) is very different from both ours.

R. corylifolius is equally common in our hedges with the *fruticoſus* [a].

14. Common Bramble has very long, trailing or rather arching, woody ſtems, of a purpliſh hue, as in

[m] Woodville and Withering. [n] Linn. ſpec. [o] Hort. kew. [p] Thunberg. [q] Willdenow. [r] Linn. ſpec. [s] Linn. ſpec. [t] Loureiro. [u] Linn. mant. [x] Swartz. [y] Smith. [z] Idem. [a] Engl. bot.

Digitized by Google

the preceding, but much more tough, with the angles more ſtrongly marked, and the prickles hooked. Leaves quinate, or ſometimes ternate; leaflets ſomewhat elliptical, doubly-ſerrate, acute, dark-green and ſhining above, white and downy beneath; but ſometimes the under ſide is merely hairy and of a paler green. All the leaflets are petioled; and the petioles are prickly. Stipules briſtle-ſhaped. Panicles many-flowered, ſubracemed, tomentoſe. Calyx ſhort, always reflexed both in flower and fruit, concave, tomentoſe. Petals pale purple, bluſh-coloured or pink; ſometimes white. Fruit of a dark violet colour, with a mawkiſh ſweet taſte, compoſed of very numerous acini or grains [b]. Gærtner deſcribes the fruit as a compound berry of an ovate-globular form, when ripe concave within and deciduous, compoſed of about fifty partial berries, which are ovate, ſucculent, very dark purple, perfectly ſmooth and ſhining; each incloſing one ſeed, which is ovate, narrowed above, compreſſed like a lens, netted and wrinkled, of a pale teſtaceous colour. The receptacle is ſhort, fungoſe, and conical.

The Bramble is found in almoſt every hedge and thicket, flowering in july and auguſt. The fruit ripens early in ſeptember. But Dr. Smith remarks, that the ſeaſon was ſo unfavourable in 1799, that ſcarcely any Blackberries were to be ſeen ripe in october. They are called in ſome countries *Bumblekites*; in others *Scald-berries*, from their ſuppoſed quality of giving ſcald-heads to children, who eat of them inordinately. The green twigs are of great uſe in dyeing woollen, ſilk and mohair black. Silk-worms will ſometimes feed upon the leaves, for want of thoſe of the Mulberry [c]. They are very aſtringent, and a decoction of them may be uſed in gargariſms.

The Bramble, ſo generally reprobated as a very troubleſome weed, may be uſeful in raiſing live hedges in a poor ſandy ſoil, in the ſhorteſt time, and at the leaſt expenſe. Several ſmall incloſures having been made in the pariſh of Cavenham in Suffolk, which is a blowing ſand, on each ſide of a narrow field-row, along which a large flock of ſheep was frequently driven; on one ſide of the road the bank was planted with Brambles mixed with the White-thorn, and a dead hedge was placed on the top, as is the uſual method in that country: the dead hedge was never renewed, and yet the fence in ten or eleven years was a tolerable one. The Bramble, which is a very faſt grower, not only defended the young quick from the ſheep, but likewiſe by twiſting itſelf through the dead hedge ſtrengthened it, and prevented its being broken down either by cattle or pilferers. On the other ſide of the road, the bank was planted at the ſame time with White-thorn only. The dead-hedge was renewed ſeveral times, and yet there was no probability that the White-thorn would ever make a fence. Mr. Le Blanc, who gives this account, improved upon the hint, by planting two rows upon a bank, the lower of Bramble only, the upper of White-thorn only. He tried this method in the years 1781 and 1782, and both fences in 1784 were more promiſing than he could have expected them to be if planted with White-thorn alone. He recommends this proceſs only in poor ſandy ſoils, where the growth of live-hedges is ſlow, where they are liable to the depredations of ſheep, and where, by reaſon of the looſeneſs of the ſoil, the ditch is no defence [d].

The ſweet Briar, or the Dog Roſe, will, either of them, aſſiſt in rearing and protecting the White thorn, in making quick hedges.]

The varieties of the Bramble are—1. That with white fruit, which has the bark and leaves of a lighter green; and was found accidentally in a hedge not far from Oxford by Bobart. 2. The Bramble with a double flower, which is introduced into plantations of ſhrubs. 3. The ſmooth Bramble without thorns. 4. With cut leaves. 5. With variegated leaves.

[15. Native of North America. It flowers here in july [e].

16. Stem purpliſh. Leaflets lanceolate, naked on both ſides, very thin, ſharply ſerrate. Bractes lanceolate. Stipules linear, prickly.—Native of Canada, where it was found by Kalm [f].

17. Root perennial, creeping. Stems many, from four to ſeven feet high, about the ſize of a man's little finger, covered with a ſmooth bark of a light brown colour, and branching out a little towards the top. Leaves ſix inches long, and ſeven inches broad, cut into three, four or five angular lobes, ending in acute points, ſerrate, having ſeveral veins ariſing from the midrib, running upwards diverging towards the borders, deep green above, but light green and ſmooth beneath; on foot-ſtalks four inches long, coming out alternately. Flowers in looſe terminating bunches, each on a long peduncle. Petals large, roundiſh, of a light purple colour [g].

The fruit is rarely produced with us, but in North America, its native country, it is like the common Raſpberry, only not ſo pleaſant. It flowers from june to ſeptember. Cornutus, who firſt figured and deſcribed this plant, gave it the name of *odoratus*, on account of the fragrance of its foliage. Nurſery-men and gardeners have named it the *Flowering Raſpberry*, becauſe it is regarded in Europe merely for its flowers, which are ſhowy, and plentifully produced in ſucceſſion, during the whole ſummer [h]. It was cultivated by Mr. Miller in 1739 [i].

18. Stem fruteſcent, decumbent, among ſhrubs or trees ſcandent. Branches upright, hirſute, with minute recurved prickles. Leaves alternate, blunt, lobed or ſublobed, ſerrate, ſmooth and wrinkled above, veined and downy-aſh-coloured beneath. Petioles tomentoſe, prickly, the length of the leaf. Flowers ſcattered in the axils and terminating, ſolitary and racemed. Peduncles tomentoſe, prickly. Calyx tomentoſe on the outſide. Corolla ſcarcely longer than the calyx [k]. Flowers in panicles. Petals ſhorter than the calyx. Germs hirſute. Styles longer than the ſtamens. Leaves tomentoſe underneath [l].—Flowers white, in oblong racemes, with torn bractes. Corolla commonly ſix-petalled. Berry ſmall, roundiſh, red [m].

Native of Amboina, Java, Ceylon, Japan and Cochinchina.

19. Stem fruteſcent, upright, from two to three feet in height. Branches round, purple, flexuoſe, with frequent ſpreading prickles. Leaves ſeveral from each bud, palmate-trifid or quinquefid, ſmooth on both ſides, villoſe-veined, ſpreading, an inch or more in length. The three lobes are commonly ſimple, but ſometimes divided again into three, lanceolate, acuminate, acutely and unequally ſerrate, the middle one longer than the others. Petioles capillary, beſet with recurved prickles the length of the leaves, unequal. Flowers from the buds among the leaves peduncled, ſolitary. Calyx villoſe, with lanceolate ſegments. Corolla biggiſh, twice as long as the calyx, white. Fruit yellow, eſculent, ſapid [n].

It reſembles the *parvifolius*, but that is hoary with down, and has the leaves always ternate, white underneath. Stems very ſmooth, round, thinly ſet with prickles. Leaves ſmall, petioled, cordate, blunt, commonly three-lobed, ſerrate, unarmed. Petioles and peduncles alſo unarmed. Flowers ſmall, the ſize of Potentilla [o].

Native of Japan, between Miaco and Quana; flowering in april [p].

20. Stem fruteſcent, ſmooth, purple, beſet with ſcattered ſpreading prickles. Branches like the ſtem, with frequent prickles. Leaves ſeveral from a bud, cordate, ovate, rounded, ſeldom acute, ſublobed, ſerrate, having raiſed nerves, unarmed. Petioles ſmooth, having recurved prickles, ſpreading, the length of the leaves. Peduncles capillary, unarmed and prickly, ſmooth, the length of the petioles. Flowers axillary, peduncled, ſolitary. Calyx ſmooth without, white-tomentoſe within. It differs from *R. moluccanus* in having an upright ſtalk and ſmooth leaves:—from *R.*

villoſus

villoſus (corchoriſolius) in having the leaves ſmooth, unarmed, blunt, gaſhed, and both peduncles and petioles longer.—Native of Japan[q].

21. This is a low ſhrub, with an upright, even, angular ſtem, not much branched. Leaves alternate, petioled, ovate or ovate-oblong, even on both ſides. Peduncle filiform, the length of the corolla. Flower the ſize of that of the Strawberry, with roundiſh white petals. Calyx ſmall[r].—Native of Japan.

22. Stem and petioles, and ſometimes under the leaves prickly. Stem, lower ſurface of the leaves, petioles, peduncles and calyxes hoary with nap. Petals ſcarcely longer than the calyx[s].

The leaves are beautifully plaited before they unfold. It differs from *R. biſpidus* in having ſimple, not ternate leaves, which are hairy: from *R. moluccanus* in having oblong-ovate acute leaves, and a ſhrubby upright ſtem.—Native of Japan, between Miaco and Jedo; flowering in april[t].

23. Stem ſhrubby, round, pubeſcent, with ſmall prickles on it. Leaves alternate, doubly and acutely crenate, ſmooth above, white-tomentoſe beneath, veined. Petioles ſhorter than the leaves, roundiſh, pubeſcent, unarmed. Panicle terminating, elongated, tomentoſe, flexuoſe, alternately branched. Pedicels cluſtered or ſolitary, ſhort, a little thickened at top, ſilky, upright. Bractes oblong, concave, pubeſcent on the outſide, toothed at top, deciduous. Calyx half-five-cleft, with blunt ſegments ending in a little point, ſilky. Petals roundiſh, white. Fruit red.—Found in Java by Commerſon.

24. Stem ſhrubby, ſubflexuoſe, round, ſlightly hirſute, with ſmall recurved prickles. Leaves alternate, ſpreading, ſmooth, except that the veins are hirſute on both ſides. Petioles ſhort, hirſute. Stipules ſcarcely any. Panicle terminating, erect, ſomewhat like a thyrſe, many-flowered, alternately branched, pubeſcent. Peduncles from the rudiments of the abortive flowers knobbed, ſubdivided. Pedicels round, ſcarcely thickened. Bractes oblong, multifid, pubeſcent, deciduous. Calyx deeply five-cleft, with the ſegments ovate, acuminate, the outer ones trifid at the top, tomentoſe on both ſides. Petals four times ſhorter than the calyx, oval, blunt, toothed at the end. Fruit compoſed of few ovate grains.—Found in Java by Commerſon[u].

25. Roots fibrous, from the joints of the ſtem, which is procumbent, round, unarmed and ſmooth. Leaves upright, ternate, with the ſide leaflets binate, thus ſeeming to be pedate. Leaflets ſhortly petioled, obovate, acutely crenate, veined, green on both ſides, naked except at the veins which are ſomewhat hairy, the outer ones often obſcurely lobed on one ſide. Common petioles very long, linear, channelled, ſmoothiſh, unarmed. Stipules in pairs, at the baſe of the petioles, roundiſh, concave, membranaceous, blunt. Flowers ſolitary, peduncled, upright, ſeemingly white. Peduncles filiform, the length of the petioles, ſubpubeſcent at top. Bractes in pairs, oppoſite, about the middle of the peduncle, blunt, ſmooth, ſmall. Leaflets of the calyx oblong, reflex, ſharpiſh, generally having a tooth or two on each ſide, veined, ſmooth or very ſlightly hairy, and not tomentoſe, as in moſt of the ſpecies. Petals the length of the calyx, obovate, ſpreading. This tender delicate plant, is diſtinguiſhed from all the herbaceous ſpecies by its leaves. It was found by Mr. Archibald Menzies, in the weſtern part of North America[x].

26. Stone Bramble has a fibroſe root, with very long, proſtrate, creeping runners, naked or leafy and barren. Stems upright, ſimple, a ſpan high, ſomewhat angular, villoſe, leafy, unarmed. Leaves ternate, (the lower ones ſometimes quinate,) pale-green, thin, doubly-ſerrate, acute, ſlightly hairy underneath, the lateral leaflets ſeſſile. Mr. Woodward has remarked all the leaflets to be ſeſſile, and alſo all on footſtalks. Panicle terminating, few-flowered, pubeſcent. Petals white, lanceolate, upright[y]. Fruit of a moſt beautiful pink colour, when ripe, of an agreeable acid flavour, and compoſed of a few (three or four) large acini[z].

Native of ſeveral parts of Europe, particularly the northern parts; alſo of Ruſſia. With us it is found in the north of England, in Scotland, Wales and Ireland; among ſtones in ſhady places on the ſides of mountains. In Yorkſhire, Cumberland, Weſtmoreland, Lancaſhire and Derbyſhire. Woods about Settle and Ingleton. Helk's-wood and Mill-bank by Ingleton. Not far from the ſummit of Helſfelnab, near Kendal. In Dob bottom, near Burnley, Lancaſhire. Hills oppoſite Matlock bath in Derbyſhire. At Dunkeld and Blair, and about Loch-Rannoch in Perthſhire. Lyn y Cwn, near Snowdon. Common in mountain glens in Ireland, near the top[a]. It flowers in june.

In Scotland they call the fruit Roebuck-Berries. The Ruſſians ferment them with honey, and extract a potent ſpirit from them[b].

27. Dwarf Crimſon Bramble has a creeping root, but no runners. Stems from a hand to a ſpan in height, upright, ſimple, angular. Leaves unequally ſerrate, commonly altogether ſmooth. Flowers ſolitary, peduncled, terminating, deep roſe-coloured, with the petals ſometimes jagged. Calyx hairy. Fruit purple, ſweet and fragrant, very pleaſant[c]; according to Linneus, almoſt as large as a Mulberry.

Linneus has figured and minutely deſcribed this arctic Bramble in his elegant Flora Lapponica, out of gratitude, as he expreſſes himſelf, for the benefit he reaped from it in his Lapland journey; it having ſo frequently recruited his ſpirits, when almoſt ſinking with hunger and fatigue, by the vinous nectar of its berries. He informs us, that the principal people in the province of Norland, make a ſyrup, a gelly, and a wine, from theſe berries, which they partly conſume themſelves, and partly ſend to their friends at Stockholm, as a dainty of the rareſt and moſt delicious kind; and he adds, that of all the wild Swediſh berries, this holds the firſt place[d].

Native of the North of Europe, Aſia and America. It has lately been diſcovered by the Rev. Dr. Walker in the Iſle of Mull.—Mr. Miller cultivated it in 1759. It flowers here in june and july[e].

28. Stem herbaceous, from flexuoſe-erect, round, almoſt ſimple, purple, ſmooth. Leaves petioled, cordate, roundiſh, trifid, ſmooth on both ſides; lobes gaſhed, unequally ſerrate. Flowers from the ſame bud with the leaves, peduncled, ſolitary; peduncle ſimple, ſeldom bifid. Petioles and peduncles villoſe, a finger's length. Calyx white-tomentoſe. Fruit red, eſculent, pleaſant taſted.

Native of Japan, near Quana; flowering in april[f].

29. Root branched, fibroſe. Stem ſimple, entirely herbaceous, ſhort, leafy, round, pubeſcent. Leaves three or four on a ſtem, alternate, ſpreading, cordate at the baſe, three-lobed, acutely and unequally ſerrate, wrinkled, naked above, paler beneath, with the veins hairy. Petioles filiform, hairy, generally higher than the ſtem. Stipules in pairs, ovate, acute, membranaceous, naked. Flower on a ſhort peduncle, terminating, ſolitary, almoſt erect, red, large in proportion to the plant. Calyx turbinate at the baſe, many-nerved, pubeſcent; with ſeven or eight linear, acuminate, very long, ſpreading ſegments. Petals as many, alternate with the ſegments of the calyx, a little longer, obovate-lanceolate, bluntiſh, ſpreading. Filaments much ſhorter than the calyx, curved inwards, continuing a long time. Anthers ſubcordate.

It is allied to *R. arcticus*, but the leaves are ſimple, and the flower almoſt ſeſſile. It is diſtinguiſhed from *R. Chamæmorus* by its appearance, but principally by the calycine ſegments being linear-lanceolate, not ovate. The calyx, together with the ſtamens of the year preceding, very frequently continues on the withered ſtem.

Mr. Archibald Menzies gathered it in the weſtern part of North America[g]. The fruit is purple, as in *R. arcticus*[h].

Digitized by Google

30. Stems herbaceous, very ſhort, depreſſed. Leaves moſtly ternate; leaflets irregularly ſerrate, very ſmooth on both ſides, veined beneath, the end one very large, cordate, emarginate. Petioles ſubvilloſe. Flowers ſolitary, on ſhort, very thick, pubeſcent peduncles. Petals roundiſh. It differs from *R. Dalibarda* in its ternate ſmooth leaves, ſerrate rather than crenate; in its ſhort thick peduncles, not filiform and very long; and its roundiſh not lanceolate petals.

Found by Commerſon in South America, at the Sraits of Magellan [t].

31. The Mountain Bramble or Cloud-berry is a plant of an elegant appearance, with a creeping root; a ſimple ſtem, hardly a foot high, upright; mallow-like, but ſmooth and hardiſh leaves, petioled, cordate, five-lobed, plaited, wrinkled, unequally ſerrate. Flowers terminal, peduncled, white; male and female, the former with ſhort abortive piſtils, the latter with abortive ſtamens. Though the plants appear to be dioecous, yet Dr. Solander affirmed that the two ſexes ſpring from one common root. The ſame has been ſaid of White Bryony. But the aſſertion has not been confirmed in either caſe. The calyx is hairy on the outſide, inflexed, with the ſegments oval or elliptical. Berries of a tawny or dull orange-colour, compoſed of many acini, acid mucilaginous and not unpleaſant [k].

Native of Sweden, Denmark, Siberia, Britain. On the higheſt mountains of the North of England, Scotland and Wales, in peat-bogs. In Yorkſhire, Weſtmoreland, Cumberland, Lancaſhire. About Settle, Ingleton and Ingleborough; near Egleſton: between Patterdale and Keſwick, Cumberland: on Axedge near Buxton, Derbyſhire: Barrowfield-wood; Cald-Kail-ſcrogs, near Kendal, in Weſtmoreland. Upon Ben-Lomond; and upon the mountains about Loch-Rannock in Perthſhire, and many other places in Scotland. In Caernarvonſhire and other counties of Wales.

From their exalted ſituation, they are called Cloud-berries; alſo Knot-berries or Knout-berries. The flowers appear in june, ſoon after the ſnow is diſſolved, and the berries are ſcarcely well ripened in auguſt, before the plant is again overwhelmed with its wintry covering. The ſnow preſerves the fruit, and is uſed by the Laplanders to keep it through the winter; for they as well as the Scottiſh highlanders eſteem it one of their moſt grateful and uſeful fruits, eſpecially on account of its long duration. Its taſte is moderately acid and mucilaginous, with ſomething of the flavour of Tamarinds [l]. They are held to be an excellent antiſcorbutic. The Norwegians pack them up in wooden veſſels, and ſend them to Stockholm, where they are ſerved up in deſerts, or made into tarts. The Laplanders bruiſe and eat them with the milk of their Rein-deer [m].

32. Root creeping, fibrous. Runners proſtrate, herbaceous. Leaves alternate, erect, obtuſe, unequally crenate, veined, having a few ſcattered hairs above, but naked beneath, reſembling thoſe of the Violet but firmer, ſometimes red. Petioles hairy, longer than the leaves. Peduncles ſolitary, leafleſs filiform hairy one-flowered, the length of the petioles. Flowers hermaphrodite, white, ſmall. Calyx five-parted, the ſegments lanceolate acute pubeſcent. Petals ovate-lanceolate, ſcarcely longer than the calyx. Filaments the length of the petals. Berry juiceleſs. Seeds five ovate ſharpiſh, in the dried plant with a corrugated ſurface [n].

Linneus makes a quere whether the flowers are not male and female on the ſame plant: and Miller aſſerts it to be ſo. Linneus remarks that the habit of this ſpecies unites it with *Rubus*, eſpecially with *R. Chamæmorus*; or elſe that both ſhould be ſeparated from this genus.

Kalm firſt brought it from Canada. It was formerly in the royal botanic garden at Kew, but periſhed, and was again introduced in 1788 from North America [o]. But Mr. Miller had cultivated it before, in 1768 [p].

Hill, in the 16th volume of his Vegetable Syſtem, t. 11. has given a figure of *R. Chamæmorus*, from Gerarde, for this ſpecies, and hence has affirmed that a very rare plant of Canada, is to be found in the northern mountains of England [q].]

PROPAGATION AND CULTURE.

4. The Raſpberry is generally propagated by ſuckers, though I ſhould prefer ſuch plants as are raiſed by layers, becauſe they will be better rooted, and not ſo liable to ſend out ſuckers as the other, which generally produce ſuch quantities of ſuckers from their roots, as to fill the ground in a year or two; and where they are not carefully taken off or thinned, will cauſe the fruit to be ſmall, and in leſs quantities; eſpecially when the plants are placed near each other, which is too often the caſe, for there are few perſons who allow theſe plants ſufficient room.

In preparing theſe plants, their fibres ſhould be ſhortened; but the buds which are placed at a ſmall diſtance from the ſtem of the plant, muſt not be cut off, becauſe thoſe produce the new ſhoots the following ſummer. Theſe plants ſhould be planted about two feet aſunder in the rows, and four or five feet diſtance row from row; for if they are planted too cloſe, their fruit is never ſo fair, nor will ripen ſo kindly, as when they have room for the air to paſs between the rows.

The ſoil in which they thrive beſt, is a freſh ſtrong loam, for in warm light ground they do not produce ſo great plenty of fruit, for they naturally grow in cold land and in ſhade; therefore when they are planted in a warm ſituation and a light ſoil, they do not ſucceed.

The ſeaſon for dreſſing them is in october, at which time all the old wood that produced fruit the preceding ſummer, ſhould be cut down below the ſurface of the ground, and the young ſhoots of the ſame year muſt be ſhortened to about two feet in length; then the ſpaces between the rows ſhould be well dug, to encourage their roots; if you bury a very little rotten dung therein, it will make them ſhoot vigorouſly the ſummer following, and their fruit will be much fairer. During the ſummer ſeaſon they ſhould be kept clean from weeds, which, with the before-mentioned culture, is all the management they will require; but it is proper to make new plantations once in three or four years, becauſe when the plants are ſuffered to remain long, they will produce few and ſmall fruit.

14. The Brambles are eaſily increaſed by laying down their branches, which will put out roots at every joint very freely. They may be tranſplanted any time from ſeptember to march, and will grow in almoſt any ſoil or ſituation. [Thus the common Bramble may aſſiſt in making or ſtrengthening a fence; and the varieties with double flowers and variegated leaves in ornamenting a plantation.

17. The Virginian Flowering Raſpberry is extremely hardy, and eaſily propagated by ſuckers: the only care which it requires, is to keep it within proper bounds. Young plants produce the largeſt and fineſt flowers; on account of which, and the largeneſs and elegant form of its leaves, it has long had a place in our ornamental plantations.

27. The dwarf crimſon or arctic Bramble grows readily and increaſes rapidly in bog-earth, on a north border; but rarely ripens its fruit in gardens [r].]

RUDBECKIA. (*So named by Linneus, from Olaus Rudbeck, father and ſon, profeſſors of botany at Upſal; the former died in 1702, the latter in 1740.*)

Lin. gen. n. 980. *Reich. n.* 1061. *Schreb. n.* 1324. *Gærtn. t.* 172. *Juſſ.* 189. Obeliſcotheca. *Vaill. act. gall.* 1720. *f.* 44. *Dill. elth.* 218.

Claſſ. 19. 3. Syngeneſia Polygamia Fruſtranea.

Nat. order of *Compoſitæ Oppoſitifoliæ. Corymbiferæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Common* with a double row of ſcales: *ſcales* flat, widiſh, curtailed, ſix in each row.

COR. *Compound* radiate: *Corollets* hermaphrodite, numerous, in a conical diſk; *Females* about twelve, very long, in the ray.

Proper of the Hermaphrodite tubular-funnel-form, with a five-toothed border. *Female* ligulate, lanceolate, with two or three teeth, flat, pendulous.

[r] Smith. [r] Curtis.

Digitized by Google

STAM. in the Hermaphrodites: *Filaments* five, capillary, very ſhort. *Anther* cylindrical, tubular.

PIST. in the Hermaphrodites: *Germ* four-cornered. *Style* filiform, the length of the corollet. *Stigma* two-parted, revolute. In the Females: *Germ* very ſmall. *Style* none. *Stigma* none.

PER. none. *Calyx* unchanged.

SEEDS in the Hermaphrodites ſolitary, oblong; crowned with a membranaceous four-toothed rim: in the *Females* none.

REC. chaffy, conical, longer than the common calyx: *chaffs* the length of the ſeeds, erect, channelled-concave, deciduous.

ESSENTIAL CHARACTER.

Cal. with a double row of ſcales. *Crown* of the ſeed a four-toothed rim. *Recept.* chaffy, conical.

SPECIES.

   Leaves oppoſite linear quite entire.

DESCRIPTIONS, &c.

1. [Mr. Miller makes two ſpecies of this: *laciniata*, n. 4. and *quinata*, n. 5. which he thus deſcribes.] The root of the former is perennial, but the ſtalk is annual. The lower leaves are compoſed of five broad lobes, deeply cut into acute points, and ſome of them jagged almoſt to the midrib; the outer lobe is frequently cut into three deep ſegments. The ſtalks riſe ſeven or eight feet high, and divide at top into ſeveral branches; they are ſmooth, green, and have ſingle, oval heart-ſhaped leaves, ſome indented on their edges, others entire. Peduncles naked, terminated by a ſingle flower with yellow rays, like the Sun-flower, but ſmaller.—The latter is alſo perennial, and has ſmooth green ſtalks; but they riſe higher. The leaves have all five lobes, which are much narrower, end with ſharper points, and are very acutely indented on their ſides. The flowers are ſmaller and the petals narrower.—They are both natives of North America: [particularly Virginia and Canada. They flower here in july. Veſpaſian Robin (ſays Parkinſon) the French King's herbariſt at Paris, had this plant from Canada, gave Mr. Tradeſcant ſome roots, and he imparted thereof to me alſo. Parkinſon therefore cultivated it before 1640[s].

Retzius ſuppoſes the *laciniata*, *quinata* and *digitata* of Miller to be mere varieties. He deſcribes two, under the names of *digitata* and *quinata*. The firſt has the ſtem obſoletely tubercled and angular, with ruſt-coloured ſpots at the inſertions of the lower leaves. Leaves wider, ſerrate; the lower quinate, the upper ternate, with the lateral lobes bifid, and the end-one three-parted; the uppermoſt leaves are ovate, entire or ſlightly trifid. Ray two inches wide, twelve-leaved. Peduncles even, grooved.—The ſecond (quinata) has the ſtem round at the baſe, angular at top, not ſpotted. Lower leaves quinate or ternate, with the lobes laciniate, narrow, toothed: the upper ternate, ſimilar: the uppermoſt three-lobed or entire, lanceolate. Ray an inch and half wide, for the moſt part ten-leaved. Peduncles ſubvilloſe, grooved.

According to Gærtner, the ſeeds of the *laciniata* are columnar or inverſely pyramidal, four-cornered, very finely ſtreaked, of a yellow bay colour, crowned with a ſhort rim, quite entire, crenulate: the chaffs on the receptacle ſometimes coloured. In ſome of the ſpecies, as *R. hirta*, he remarks, that the rim on the ſeed almoſt vaniſhes, or is even quite wanting.]

2. This has a perennial root like the former. The leaves at bottom are compoſed of ſeven or nine lobes, ſome entire, others jagged to the midrib; they are of a dark green and ſmooth. The ſtalks riſe ſix feet high, and divide into many branches; they are of a purple or iron colour, and are very ſmooth. The ſtem-leaves, towards the bottom, are hand-ſhaped, and compoſed of five lobes; higher up they have but three lobes, and at top the leaves are ſingle. The flowers are ſmaller than thoſe of the preceding, but of the ſame ſhape and colour.

[Native of North America. Cultivated in 1759, by Mr. Miller. It flowers in auguſt and ſeptember [t].] Mr. Miller ſays that he had the ſeeds from Siberia, as well as North America.

3. This is a biennial plant. The lower leaves are divided into three lobes, but thoſe upon the ſtalks are undivided; they are hairy, and ſhaped like thoſe of the firſt ſort. The ſtalks branch out on their ſides, and are better furniſhed with leaves than the others. The flowers are very like thoſe of the firſt ſort, but ſmaller. It grows naturally in ſeveral parts of North America.

[According to Linneus, the ſtem is panicled and many-flowered.—The ſeed was ſent by Baniſter from Virginia, and was cultivated in the botanic garden at Oxford [u].]

4. The root of this will continue four or five years. The leaves are oblong, ovate and hairy. The ſtalks riſe a foot and half high, and have one or two leaves near the bottom. The peduncle is naked near a foot in length, and is terminated by one pretty large yellow flower, ſhaped like the Sun-flower. The florets of the ray are very ſtiff, and ſlightly indented at their points: the diſk is very prominent, and of a dark purple colour. The flowers will continue ſix weeks, and there is a ſucceſſion of them from the middle of july, till the froſt puts a ſtop to them.—Native of Virginia and ſeveral other parts of North America.

[Cultivated in 1732, by James Sherard, M.D. in his garden at Eltham in Kent.

5. Native of North America. Introduced in 1760, by Meſſrs. Kennedy and Lee. It flowers in july and auguſt [x].]

6. This is a perennial plant like the fourth. The leaves are longer and broader, are ſmooth, and have three veins. The peduncles are taller, and have two

[s] Hort. kew. [t] Idem. [u] Bobart in hiſt. oxon. [x] Hort. kew.

Digitized by Google

of three narrow leaves on each, placed alternately. On the top is one flower, with long narrow, reflexed, peach-coloured florets in the ray: the disk is very prominent, and of a dark purple colour. It flowers at the same time with the fourth, but the flowers are not of so long duration.

[It is easily distinguished from the other species, by the long narrow purple pendulous florets of the ray.—It is a native of Carolina and Virginia; and was introduced before 1699, by the Rev. John Banister[y].]

7. Root perennial. Stalks four or five feet high. Leaves narrow, smooth, opposite. Florets in the ray of the flower yellow, long, twelve in number: disk dark red. Scales of the calyx spreading and almost awl-shaped.

Native of Virginia. [Cultivated in 1758, by Mr. Miller. It flowers in august and september[z].]

PROPAGATION AND CULTURE.

1. 2. These do not produce seeds here, but are easily propagated by parting the roots. It is hardy, and loves a moist soil.

3. In warm summers this perfects its seeds in England. The plants will live through the winter in the open air, in mild seasons, and may be increased by slips or heads; but the best way is to raise the plants from seeds: the second year the seedling plants will flower, and produce ripe seeds.

4. The root of this will continue four or five years, but unless care be taken to shelter it in winter, it is sometimes destroyed by cold and too much wet. It sometimes produces good seeds in England, in a favourable season; but it is generally propagated here by offsets or slips, unless seeds can be procured from America.

The best time to separate the offsets is in the spring. The plants will live abroad in the open air through the winter, in a dry soil and warm situation; but it will always be prudent to shelter two or three plants under a common hot-bed frame to preserve the species, for in severe winters they are often killed.

The same directions may serve for the fifth and sixth sorts, but they rarely produce seeds in England; nor do the plants put out heads, whereby they may be increased that way.

7. This, together with the first and second sorts, may be propagated in plenty by parting the roots in october, when the stalks begin to decay. They love a moist soil, and should be allowed room, for if they are too near other plants, they rob them of their nourishment. They are proper furniture for large gardens or plantations.

RUELLIA. (*So named by Plumier, in memory of Joannes Ruellius, physician at Paris; author of a treatise* De Natura Stirpium, Par. 1536. fol. *He died in* 1537.)

Lin. gen. n. 784. *Reich. n.* 847. *Schreb. n.* 1050 *Gærtn. t.* 54. *Plum.* 2. *Dill. elth.* 248, 249. *Juss.* 103.

Class. 14. 2. Didynamia Angiospermia.

Nat. order of *Personatæ*. *Acanthi*, Juss.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, five-parted, permanent: *segments* linear, acute, straight, permanent.

COR. one-petalled, irregular, with a patulous inclined *neck*: *border* five-cleft, spreading, blunt; with the two upper segments more reflexed.

STAM. *Filaments* four, placed where the tube widens, approximating by pairs. *Anthers* scarcely longer than the tube.

PIST. *Germ* roundish. *Style* filiform, the length of the stamens. *Stigma* bifid, acute; the lower segments rolled in.

PER. *Capsule* round, acuminate both ways, two-celled, two-valved, opening elastically by the claws: *partition* contrary.

SEEDS a few, roundish, compressed.

OBS. *In some species there is the rudiment of a fifth stamen.*

ESSENTIAL CHARACTER.

Cal. five-parted. *Cor.* subcampanulate. *Stam.* approximating by pairs. *Capsule* opening by elastic teeth.

SPECIES.

[1. Ruellia Blechum. *Hairy-leaved thick-spiked Ruellia. Swartz, obs.* 243.

Leaves ſeſſile oblong bluntly ſerrate, flowers axillary ſolitary ſeſſile.
43. Ruellia rupeſtris.
Swartz, prodr. 93.
Stemleſs, leaves petioled oblong crenate-waved, ſcapes erect many-flowered.

DESCRIPTIONS, *&c.*

The *Ruelliæ* are very nearly allied to the *Juſtitiæ*, in their natural order, flowers, fruit and habit[a]. The caſe is the ſame in ſeveral other genera of the claſs Diandria: and in *Verbena* ſome ſpecies belong to this, and others to that claſs.

1. Stem herbaceous, a foot high, upright, branched, four-cornered, ſtriated, even. Branches ſpreading, oppoſite, axillary. Leaves petioled, oppoſite, ovate-lanceolate, acuminate, nerved. Spikes terminating, four-cornered, conical, an inch long. Bractes imbricate, or floral leaves cordate, acuminate, nerved, hirſute; at the baſe of which are two little lanceolate bractes, and within them three ſubſeſſile flowers, ſmaller, whitiſh-blue. Calyx five-leaved; leaflets awl-ſhaped, erect. Corolla funnel-form; tube narrower at the baſe, ſomewhat bell-ſhaped above the middle, gibbous behind; border three-cleft, ſegments equal, oblong, the two hinder ones more upright. Two of the filaments the length of the tube. Anthers awl-ſhaped, upright. Germ oblong, acuminate. Style the length of the tube. Capſule ſubpedicelled, ſurrounded by the calyx at the baſe, ovate. Seeds black. It is an annual plant, common in paſtures and buſhy places in Jamaica.

The deſcription of R. Blechum in Amoen. acad. ſeems rather to belong to the next ſpecies, which Linneus has probably confounded with this[b].

2. Stems proſtrate, dichotomous, even, ſlightly four-cornered. Leaves oppoſite, ovate, ſcarcely pubeſcent, quite entire, toothlets obſolete. Petioles ciliate. Spikes

[a] Swartz, obſ. 246. [b] Idem, ib.

looſe,

Digitized by Google

looſe, four-cornered, made up of cordate floral leaves, with two ſhort lanceolate bractes within each, and within theſe two ſeſſile flowers, one without the other [c].

Browne ſays, that this plant is pretty frequent in moſt dry and ſhady places, among the lower hills in Jamaica; that it thrives beſt in a gravelly ſoil, but ſeldom riſes above two feet and a half in height.—Introduced in 1780, by Monſ. Thouin [d].

3. Native of the Weſt Indies [e].]

4. Root fibrous, perennial. Stems about a foot high, four-cornered with two longitudinal furrows, one on each ſide; the joints are three or four inches aſunder, and at each two oval leaves upon very ſhort foot-ſtalks. Flowers axillary, two or three from the ſame point, ſitting very cloſe to the ſtalk, ſmall, of a pale purple colour, and very fugacious; opening early, and gone by ten or eleven in the forenoon. Capſules ſhort, taper, ſurrounded by the hairy ſegments of the calyx.

[Angles of the ſtem green. Leaves lanceolate-ovate, very bluntly ſerrate, much veined, remote at the baſe, and very ſlightly ciliate. Peduncles oppoſite, lateral. Bractes two, oppoſite, and two alſo under each lateral flower. Calyx five-parted, lanceolate. Corolla pale with a blueiſh palate. Filaments, of each ſide, connected at the baſe, by the mediation of a membrane [f].

It has the epithet *ſtrepens* from the craſhing ſound which the leaves make, when handled, on account of their very dry nature [g].

Capſule oblong, acuminate at top, ventricoſe in the middle, rounded-four-cornered, lengthened out at the baſe into a compreſſed elaſtic claw, two-celled, two-valved: partition bifid, contrary, accompanied by the hooked, channelled, alternating retinacula of the ſeeds; which in each cell are three to five, rounded-cordate, rugged with very minute briſtles preſſed cloſe to them, ſlightly convex on one ſide, flattiſh on the other, brown-aſh-colour, ſeſſile in the axils of the retinacula [h].

Native of Virginia and Carolina. Cultivated in 1726, by James Sherard, M.D. at Eltham. It flowers in july and auguſt [i].

5. Stem four-cornered, pubeſcent, ſeemingly herbaceous. Leaves about a ſpan in length, running down a little along the petiole, having a few ſmall hairs ſcattered over them on each ſide, paler beneath. Petioles pubeſcent, an inch and half long. Peduncles oppoſite, the length of the leaves, round, pubeſcent, bifid. Pedicels in pairs, half an inch long, one-flowered, having a lanceolate ciliate bracte at the baſe on each ſide longer than the pedicels, and two others at the baſe of each calyx, and of the ſame length with it. Calyx ſmooth, with the five ſegments lanceolate and nearly equal. Corolla ſmooth, narrowed at the baſe, widening gradually upwards: ſegments quite entire, the two upper ones rounded, the three lower a little ſhorter and ovate. Filaments the ſame length with the corolla; and the ſtyle longer.—Native of the iſland of Santa Marta [k].

6. Shrubby, the whole plant very fetid, inſipid, and ſomewhat villoſe, as is alſo the calyx. Stem a foot high and more, round, viſcid, upright, with decuſſated branches ſpreading at an acute angle, from the very bottom. Leaves rounded-ovate, blunt, oppoſite, petioled, thickiſh. Floral-leaves lanceolate and ſharpiſh. Flowers ſubſeſſile, in threes or fives. Leaflets of the calyx awl-ſhaped and ſhort. Corolla dirty fleſh-colour; tube cylindrical, throat bell-ſhaped, border ſpreading very much, with roundiſh ſegments, the two upper ones a little leſs than the other three. The corolla emerges from the calyx in the evening, is fully expanded next morning, and falls before night. Anthers upright, acute and white. Style hairy. Stigma bifid, with the upper ſegment obſolete, but the lower protracted into a lip, and appearing with a magnifier to be rough-haired. Capſule wedge-ſhaped, acute, ſmooth, brown, compreſſed, thrice as long as the permanent calyx, two-celled, two-valved, with elaſtic claws. Seeds in each cell commonly ſix, orbicular, convex a little on one ſide, flatted on the other, ſhining. Native of the Eaſt Indies [l].

7. Stem obſcurely four-cornered, with a groove in each ſide. Leaves an inch long, ovate-oblong, bluntiſh, pale green, ſmooth. Peduncles very ſhort, oppoſite, one-flowered; having a lanceolate ciliate leaf, longer than the calyx, on each ſide at the baſe of the calyx. Tube of the corolla three times as long as the calyx, widening upwards. Flowers large, violet-coloured [m].]

8. Root perennial, compoſed of many fleſhy fibres. The leaves and ſtalks lie cloſe to the ground; the ſtalks are five or ſix inches in length; the leaves, placed by pairs at each joint, are two inches long, and an inch and quarter broad, on foot-ſtalks half an inch in length. Peduncles naked, dividing into two ſmaller ones, each ſuſtaining one ſmall purple fugacious flower; calyx cut into very narrow ſegments to the bottom. Capſule taper, about an inch long.

[Native of Barbadoes, where they call it *Snap-dragon*, from the burſting of the ſeed-veſſels. It flowered firſt in the month of auguſt 1728, in Sherard's garden at Eltham; the following year in june and july [n].]

9. Root perennial. Stems four or five feet high, much diffuſed. Leaves oblong, oval, entire, oppoſite, on ſhort hairy foot-ſtalks. Flowers at the diviſions of the ſtem, ſmall, purple, of ſhort duration.

[Stem ſuffruteſcent, from two to three feet high, branched, often proſtrate, four-cornered, ſmooth, but pubeſcent towards the top. Leaves oppoſite, on ſhort petioles, ovate-lanceolate, ſubſerrate, nerved, ſomewhat hirſute or rugged; ſtem-leaves larger; branch-leaves often deciduous. Panicles formed of oppoſite dichotomous branches divaricating very much; pedicels one-flowered; flowers biggiſh, blue. Capſule acuminate, ſurrounded by the calyx, two-celled, burſting by the claw. Seeds roundiſh, compreſſed, black. The whole herb is ſomewhat clammy with glands, and has an odour approaching to that of Camphor.

Native of Jamaica, in the ſouthern parts, on dry hills and in hedges [o]. Cultivated by Mr. Miller in 1768.

Dr. Patrick Browne ſays, it is very common about Spaniſh Town, and in many other parts of the low lands; where it generally blows in the months of december and january; making a very beautiful appearance among the buſhes, in that bleak ſeaſon of the year. Hence they call it *Chriſtmas Pride*. Being weakly, it ſeldom riſes above a foot or two, if alone; but when ſupported, it runs frequently three or four feet, and bears a great number of flowers.

10. Stem herbaceous. Branches bluntly four-cornered, hairy, jointed; joints two inches long, thickened at the baſe. Leaves on ſhort petioles, quite entire, acute, an inch in length. Spike terminating, two inches in length. Flowers ſolitary, alternate, or very rarely oppoſite. Bractes two, briſtle-ſhaped, at the baſe of the flower. Calycine ſegments lanceolate-awl-ſhaped, hairy. Corolla violet-coloured, pubeſcent on the outſide [p].]

11. The roots are compoſed of many ſwelling fleſhy tubers, which run deep into the ground, and are like thoſe of the Day Lily (Hemerocallis,) but ſmaller. Stem four or five inches high, ſending out two or three ſhort ſide-branches. Leaves oppoſite, ſome ſmall and ſhaped like a ſpatula, others much larger; they have ſhort foot-ſtalks, and are a little crenated on their edges. The flowers are produced on the ſide and at the end of the ſtalk; thoſe on the ſide have two flowers upon each peduncle, which come out oppoſite at each joint, but thoſe at the top ſuſtain three. The flowers have narrow tubes about an inch long, then ſpread out to a ſort of bell-ſhape, and at the top are cut into five large blunt ſpreading ſegments; they are of a fine blue, but ſeldom laſt in beauty through the day. Capſule an inch and half long, taper.

[Tubers of the root oblong ſmooth. Stem herbaceous, undivided, upright, from ſix inches to a foot

[c] Linn. [d] Hort. kew. [e] Swartz. [f] Linn. mant. [g] Dillenius. [h] Gærtner. [i] Hort. kew. [k] Vahl. [l] Jacquin. [m] Vahl. [n] Dillenius. [o] Swartz. [p] Vahl.

in height, four-cornered, ſmooth, but pubeſcent at top. Leaves wedge-ſhaped at the baſe, ovate, nerved, ſmooth. Peduncles axillary, oppoſite, ſpreading, ſeldom ſimple, commonly three-parted, the length of the leaves, ſometimes trichotomous. Flowers large, blue. Capſule oblong, acuminate. Seeds roundiſh, black [q].

This plant is very common in moſt parts of Jamaica, where it is called *Menow-weed*, *Spirit-weed*, and *Snap-Dragon*. It is ſeldom more than twelve or ſixteen inches high. The roots are frequently uſed in fevers, among the negroes: when freſh, they have a little pungency, but when dry they are quite inſipid [r].

Cultivated by Mr. Miller in 1759.

12. Native of the Eaſt Indies.

13. Stem pubeſcent. Leaves oppoſite, ſubſeſſile, lanceolate, having two or three teeth on each ſide, acuminate, ciliate. Flowers axillary, ſeſſile. Calyx ciliate at the angles, with ſhort teeth [s].

Stem herbaceous, annual, eight inches high, angular, grooved, branched, diffuſed, creeping. Leaves ovate, ſubpetioled. Flowers white-violet, ſolitary, on long peduncles. Capſule ovate, many-ſeeded. Burman's figure, though quoted by Linneus, by no means agrees with his deſcription, or with the plant of Cochinchina [t].—Native of the Eaſt Indies and Cochinchina.

14. Leaves much ſmaller than in the *ſtrepens*, and not ſo hairy. Flowers ſmaller, and two only from each axil.—Native of Carolina [u]. Introduced in 1765, by Mr. John Cree [x].

15. Root woody, creeping. Stems a finger's length, quite ſimple, jointed, roundiſh. Leaves ſubpetioled, having hairs ſcattered over them, the edge turned back waved curled or crenate. Heads of flowers at the joints, lateral, ſolitary, imbricate with ovate acuminate hairy-rugged leaves, within which are the flowers, having a five-parted hirſute linear calyx, and a yellow corolla [y].

This plant is a ſuffrutex, and has the appearance of yellow Cock's-comb (Rhinanthus Criſta galli.) It is rough and lies on the ground. It grows on open hills in China; and the Chineſe name is *Patt-fa* [z].]

Mr. Miller ſays, that it grows naturally in both Indies; and that he received ſeeds of it from Carthagena in New Spain. [If it be his plant, he cultivated it in 1759.

16. Stems herbaceous, filiform, weak, decumbent, angular with decurrent lines, alternately branched, jointed; the joints rough-haired, jointed. Leaves oppoſite, remote, an inch long, one ſmaller than the other, hairy underneath, nerved, tender, remote, toothletted, acute. Petioles the length of the leaves, winged by the decurrent baſe of the leaf, wider above. Flowers from the upper axils and top of the branchlets, collected into a ſmall faſtigiate peduncled head. Bractes three at the baſe of each flower; the outer membranaceous, three-nerved, hairy, oblong, acute, three times as wide as the others; the ſecond of the ſame length, coloured, nerved, netted, lanceolate; the third ſhorter and narrower. Calyx hairy; the ſegments coloured, membranaceous, netted, three-nerved, acute: the upper one linear-lanceolate, wider than the reſt; the two lateral ones briſtle-ſhaped, ſhorter; the two lower the ſame length with the upper one, but a little narrower. Corolla longer than the calyx, ſmooth; lower lip three-lobed, with the lobes rounded [a].

Found by Koenig, in woody places, near the hot baths of Trinquemala, in the iſland of Ceylon [b].

17. The whole plant villoſe and ſoft. Branches roundiſh. Leaves oppoſite, remote, pendulous, a hand or more in length, an inch in width, attenuated at the top, alternately veined, on aſh-coloured petioles. Flowers collected into a peduncled bundle: peduncles oppoſite on the uppermoſt axils and at the ends of the branches. Bractes three, minute, awl-ſhaped, at the baſe of the calyx; which is cylindrical and hairy: the five ſegments are linear, acute, the two outer larger than the others.—Native of Madagaſcar. *Thouin.*

18. Stem herbaceous, ſmooth, four-cornered, with the corners blunt, and a wide deep groove on each ſide; the joints thicker and hairy-ciliate. Branches oppoſite, ſhorter than the ſtem. Leaves two inches long, and an inch and half wide, blunt, narrowed at the baſe, flat, veined, ſmooth, paler underneath. Petiole an inch long, margined above by the decurrent leaf, ciliate at the baſe. Flowers cluſtered in alternate heads. Outer bractes ſix, ciliate, ovate-lanceolate, bluntiſh; inner narrower, lanceolate. Calycine ſegments five, ciliate, awl-ſhaped; the two lower deeper and ſhorter. Corolla a little longer than the calyx and ſmooth.—Found in the Eaſt Indies by Koenig.

19. Stem upright, obſcurely four-cornered by four decurrent lines, two of the ſides wider and more convex; with ſhort branches, ſome alternate others oppoſite. Leaves ſubſeſſile, oppoſite, a long ſpan in length, an inch in width, drawn to a point at both ends, bluntiſh, flat, paler underneath, alternately nerved, ſmooth on both ſides. Flowers imbricate, in a ſhortly peduncled head, the ſize of a hazel nut. Bractes four under each head, ovate, acute, hairy, ciliate, ſhorter than the head; three at the baſe of each flower, the length of the calyx, hairy; two on the ſides, linear-lanceolate; the outer oblong, three times as wide as the others. Calycine ſegments five, unequal, linear, acute.—Found in the Eaſt Indies by Koenig [c].

20. Herb creeping. Stems herbaceous, filiform, jointed, even. Leaves oppoſite, blunt, ſmooth; ſpikes axillary, peduncled; flowers oppoſite: bractes linear, ſhorter: calyxes hairy-awned.—Native of Java [d].

21. Procumbent. Stems a ſpan long, jointed. Leaves lanceolate, bluntiſh, ſmooth, with the edge a little repand, or ſo obſcurely crenate that it ſeems to be entire, petioled. Bractes two, ſeſſile, ſhorter than the calyx, the leaflets of which end in ſubvilloſe briſtles [e].—Native of the Eaſt Indies, Ceylon and China.

22. This has the appearance of Veronica officinalis, but much ſmaller; or of Verbena nodiflora. Leaves oval, narrower at the baſe, ſharply and deeply ſerrate, eſpecially towards the end. Panicle or ſpike compoſed of oppoſite peduncled flowers, five together. Capſules awl-ſhaped, three times as long as the calyx [f]. Calyx four-cleft. Corolla four-lobed, unequal. Seeds many, oblong [g].

Stem herbaceous, annual, five inches high, round, creeping, with diffuſed branches. Leaves ovate-lanceolate, ſerrate, ſmooth, ſeſſile. Flowers white-violet, on many-flowered peduncles. Calyx five-cleft, acute, erect, permanent. Corolla ringent, five-cleft. Capſule awl-ſhaped, long, round, many-ſeeded.

Rumphius deſcribes his *Cruſta ollæ major* with many-flowered, ſubterminating peduncles, like this; but figures it with ſolitary, axillary flowers, more like the *ciliaris* [h].

Native of the Eaſt Indies, China and Cochinchina.

23. Stems a hand high, herbaceous, creeping. Flowers lateral, ſolitary. Bractes in pairs, elliptic [i].—Native of the Eaſt Indies.

24. Shrubby, very much branched, depreſſed. Branches four cornered, jointed, whitiſh. Leaves in bundles on the runners, ſmall, on ſhort petioles, rigid, remotely ſerrate, ſomewhat fleſhy, dotted, ſprinkled with a hoary meal. Calyx five-cornered, tubular, five-cleft; the ſegments ſtriated, acute, hoary. Corolla tubular: border bell-ſhaped, angular, veined, five-cleft; the ſegments unequal. The two large ſtamens have a toothlet at the baſe. Capſule linear-oblong, longer than the calyx.

Found by Koenig near Sadraſs in the Eaſt Indies, on the coaſt; and very common where the lands are inundated in the rainy ſeaſon [k].

25. Stem upright, ſomewhat rugged, with long hairs ſtanding out, mixed with others that are very ſhort, and ſtellate. Leaves very blunt, veinleſs, covered on both ſides with ſtellate hairs, paler underneath, an inch long. Petioles ſhorter than the leaf, hairy. Flowers on a peduncle half an inch in length.

At the base of the calyx are two petioled leaflets, very like the stem-leaves but smaller. Calyx bell-shaped, five-cleft: segments ovate, acute, within hoary and very soft. Tube of the corolla four inches long, villose at top: border bell-shaped, five-cleft, with equal, rounded segments. Filaments almost equal. Capsule oblong, sharp at both ends.

This is very different from *Barleria longiflora* of Linneus's Supplement; for that has very soft leaves, without stellate hairs; smooth, netted, sessile, scarious bractes [l].

26. Leaves lanceolate, narrow, entire, some serrate, others deeply toothed, with sharp teeth.—Native of the East Indies [m].

27. Stem herbaceous, four-cornered, with the corners blunt, grooved on both sides, having hairs scattered over them so small as to be scarcely visible; jointed, the joints thicker at top. Branches few, short, alternate, of the same structure with the stem. Leaves sessile, two inches long or less, bluntish, a little narrowed at the base, of the same colour on both sides, flat, spreading: the younger ones hairy, especially at the edge. Flowers axillary, sessile, three on each side. Bractes, one at the base; those of the calyx oblong, narrowed at the base, blunt. Calyx tubular, five-cleft, on the outside pubescent, ash-coloured: segments linear-lanceolate, acute, equal. Upper lip of the corolla undivided, compressed, lanceolate, blunt: lower with long hairs scattered over the upper surface, trifid; the segments linear, blunt. Anthers two-awned at the base. Native of the East Indies.

28. Allied to the preceding; but differing in having the stem almost simple; the leaves longer, more attenuated at both ends, and not at the tip only, having lines resembling hairs scattered over both sides, pale green underneath, all nearly of the same length, and not smaller, oblong and blunt, on the branches. Bractes not leafy blunt, but linear-lanceolate acute, not attenuated at the base. Finally, the calyxes are smaller, and end in a bristle, and have subciliate hairs at the edge only, not all over, permanent even to the falling of the fruit.—Native of the East Indies [n].

29. Stems four-cornered, jointed, fleshy, coloured. Leaves spreading, lanceolate-oblong, very finely serrate, smooth, glutinous. Bractes quite entire, often ciliate. Four segments of the calyx lanceolate; the fifth upper one wider. Corolla ringent, yellow. Anthers blueish. Style rough-haired. Very common in rice fields in the East Indies, especially when the harvest is over. It has a strong smell of turpentine.

30. This is a small plant, flowering in january and february. Very common in Tranquebar, &c. in rice fields. These two were found by Koenig [o].

31. Stem herbaceous, rough with white hairs, scarcely a span high, branched, four-cornered. Branches opposite, quite simple, shorter than the stem. Leaves quite entire towards the base, but outwardly serrate, blunt. Spikes solitary at the ends of the branches, and opposite from the last axils, imbricate with bractes and flowers, an inch long, on short peduncles. Bractes oblong, the length of the calyx. Segments of the calyx linear.—Native of the East Indies [p].

32. Native of the Cape of Good Hope.

33. Native also of the Cape, where these two were found by Thunberg. This is singular in having the stem pressed close to the ground [q].

34. Stem shrubby. Branches jointed; the upper ones subdichotomously branched, obscurely four-cornered. Leaves quite entire, acute, greener above, nerved, appearing to be marked with paler lines resembling hairs, when examined by a magnifier, underneath hoary. Flowers four or six in a short terminating spike, opposite, distant, seldom in pairs, sometimes the opposite one is wanting. Bracte linear, the length of the calyx. Tube of the corolla filiform, longer than the calyx.

Native of the East Indies, whence it was sent with many other rare plants by Roetel.

35. Stem, branches, leaves and petioles pubescent. Leaves an inch long, blunt; the younger ones hoary, a little acuminate. Petioles spreading very much, a little shorter than the leaf. Racemes almost a span long: pedicels short, remote. Bractes bristle-shaped, shorter than the pedicel. Calyxes rough-haired. Corollas smooth, yellow. Germ villose, hoary. It differs from the *intrusa* in having the corollas larger, in racemes, yellow, and the segments of the border roundish. Found in the East Indies by Koenig [r].

36. Stem herbaceous, four-cornered, brown, upright. Leaves subpetioled, bluntish, quite entire, veined, smooth, spreading, small, the upper ones gradually less. Spikes several, terminating, alternate, smooth, a finger's length. Bractes entire, imbricate-spreading, the same length with the tube of the corolla. Corolla bell-shaped, yellow; the border equal.—Native of Japan [s].

37. Stem suffruticose. Branches four-cornered, hairy, especially under the joints. Leaves an inch long or more, bluntish, sharp at the base, veinless, having fewer hairs above. Petiole scarcely half an inch long, rough-haired. Spike peduncled, upright, an inch and half in length. Flowers alternate. Bractes three at the base of each flower, lanceolate, attenuated, somewhat rough-haired, ciliate, longer than the calyx, unequal; the outer a little wider and longer than the two others. Calycine segments awl-shaped, smoothish. Corolla smooth.—In Forskahl's herbary there is another plant, which is smooth all over, with the petioles a little longer, and the leaves wider, in all other respects resembling this.

38. Stem suffruticose. Branches weak, brachiate, four-cornered; corners sharp reverse-haired. Leaves an inch long, one half the size of its opposite, acuminate, veined, somewhat hairy. Petiole half an inch long, loose, pubescent. Spikes from the end of the branches and branchlets, an inch or more in length, hairy. Floral leaves at the back of the spike, oblong, sharpish, shorter at the base on one side, of the same consistence with the leaves on the stem. Anterior bracte cordate, membranaceous, very hairy, netted-veined. Flowers three or four under each bracte. At the base of the calyx a smaller bracte, which is ovate, and of the same structure with the outer one. Calycine segments hairy, unequal: the upper one ovate, membranaceous, netted, longer than the rest, and five times as wide; the two lateral ones bristle-shaped; the two lower ones a little wider and longer than the lateral ones. Corolla a little longer than the outer bracte [t].

According to Retzius, the flowers are white and nocturnal.

Native of Arabia Felix, the East Indies, and the Isle of Bourbon [u]. Koenig sent it from Bengal [x].

39. This is a little shrub, with the branches round at bottom, smooth, covered with an ash-coloured smooth bark, villose at the end. Leaves petioled, half an inch long, blunt, quite entire, thickish, veinless, marked with lines above, having small hairs pressed to the surface scattered thinly over them, underneath more hairy, canescent. Head of flowers hemispherical, surrounded at the base by a few oblong leaflets. Bractes three, lanceolate, membranaceous nerved, ending in an awn, hairy-ciliate. Calycine segments membranaceous, terminated by an awn two lines long, nerved, hairy, ciliate, unequal: the upper one oblong, four times as wide as the others, netted; the two lateral ones awl-shaped, shorter by half; the two lower ones of the same length with the upper, linear-subulate. Corolla hairy on the outside. Capsule smooth, oblong, acute, shorter than the calyx. Found in Arabia Felix by Forskahl.

40. Stem herbaceous, slightly four-cornered, smoothish, branched. Leaves petioled, an inch or a little more in length, rather attenuated at the base, sharpish, nerved, almost veinless. Spikes from the end of the branches, peduncled, scarcely an inch long, oblong, imbricate, the thickness of a swan's quill. Bractes two at the base of the calyx, awl-shaped.

[l] Vahl. [m] Linn. suppl. [n] Vahl. [o] Linn. suppl. [p] Vahl. [q] Linn. suppl. [r] Vahl. [s] Thunberg. [t] Vahl. [u] Idem. [x] Retz.

Calyx five-leaved: four of the leaflets awl-ſhaped; the fifth a little longer, linear-lanceolate awned, ſomewhat veined; all membranaceous, pale, with three deeper-coloured lines, and ciliate. Found in Montſerrat by Ryan[y].

41. Native of the iſland of Tanna.

42. Native of the iſland of Otaheite[z].

43. Native of Hiſpaniola[a]. By the note of interrogation, I ſuppoſe that Swartz doubts whether this be a Ruellia.]

PROPAGATION AND CULTURE.

Theſe plants are propagated by ſeeds, which muſt be ſown early in the ſpring in pots filled with light rich earth, and plunged into a moderate hot-bed; and when the plants come up, they muſt be tranſplanted each into a ſeparate ſmall pot filled with rich earth, and plunged into a hot-bed of tanner's bark, where they muſt be ſhaded from the ſun until they have taken new root; after which time they muſt have free air admitted to them every day in warm weather, and be conſtantly watered three or four times a week during the ſummer ſeaſon. If the plants thrive well, thoſe of the 8th and 11th ſorts will produce flowers the july following, and will perfect their ſeeds in auguſt; but the roots will continue, provided they are plunged into the bark-bed in the ſtove, and kept in a moderate temperature of heat.

The 4th ſort is not a plant of long continuance, ſeldom abiding longer than two years; but if it is treated in the ſame manner as the two other, it will ripen ſeeds the ſecond year, ſo may be propagated eaſily.

The 15th ſort does not ſo conſtantly produce ſeeds as the three others, and therefore is not ſo common in England at preſent. This requires the ſame treatment as the other ſorts.

If the ſeeds are permitted to ſcatter, as their pods diſcharge them with a violent ſpring into the neighbouring pots, the plants will come up without care, and may be tranſplanted into pots filled with freſh loamy earth, and plunged into the tan-bed.

Flowers dioecous, valves naked, ſtem prickly.]

DESCRIPTIONS, *&c.*

1. Patience Dock has a large root, dividing into many thick fibres, which run downwards; the bark is brown, but the inſide is yellow, with ſome reddiſh veins. Leaves broad, long, acute-pointed, on petioles of a reddiſh colour. Stems from four to ſix feet high, dividing towards the top into ſeveral erect branches, having a few narrow leaves on them, and terminated by ſpikes of large flowers, which appear in june.

[The ſeminal leaves are ſagittate, like the leaves of *R. Acetoſa* or Sorrel. The ſtem is grooved [b].

Valves of the calyx larger, ovate, netted-veined. Seed ovate-acuminate, very ſharply three-ſided, of a bay colour, and ſhining [c].

Gærtner conſiders what Linneus calls the corolla, as a part of the calyx. According to him therefore, the flowers in this genus have a ſix-leaved calyx, and no corolla. He remarks that the embryo, in this and all the ſpecies is *peripherical*, or placed by the ſide of the albumen.

Native of Italy, Heſſe and ſome other parts of Germany. It was cultivated by Gerarde in 1597 [d];] the herb being formerly uſed in the kitchen, by the name of Patience; and alſo in medicine, as Monk's Rhubarb, which is the *R. alpinus*. It is now wholly neglected, and therefore ſeldom ſeen in gardens at preſent.

2. [Root fuſiform. Stem upright, branched, angular, leafy, ſmooth. All the leaves petioled, ſmooth, veined, ſomewhat curled about the edge: the root-leaves very large, cordate at the baſe. Racemes terminating, ſpreading, almoſt leafleſs; with the flowers in alternate bundles, pedicelled, nodding. Calyx quite entire. Petals oblong, quite entire, permanent, and conſtituting the valves which embrace the ſeed: one of them, and ſometimes all, becoming graniferous. Seed ſmall, ſharply three-ſided. The veins and petioles of the leaf abound in a blood-coloured juice [e].

According to Gærtner, the valves of the calyx (corolla) when ripe are ferruginous, ovate, quite entire, ſmall, all graniferous, or only two, or even but one; one grain however is conſtantly larger than the reſt, and reddiſh-brown. The ſeed is ſmall, brown, and ſhining. The embryo is lateral, but ſcarcely curved in a very ſlight degree.

Gerarde ſays it was ſown in his time for a pot-herb in moſt gardens.—It is ſaid by Linneus to be a native of Virginia; whence it migrated to England, and was firſt obſerved by Merret, in woody places about Hampſtead.

It has been ſince found by Mr. Hudſon about Maidſtone; by Dr. Sibthorp, on Headington-hill, near Oxford; by Dr. Smith, at Loweſtoft in Suffolk, and about Briſtol; near Harefield in Middleſex, by Mr. Blackſtone.

β. The green-veined Dock, ſo frequent in ſhady places, differs in no reſpect from the blood-wort, except in the colour of its veins.

Mr. Curtis and Dr. Withering have confounded this variety with the true *R. acutus* of Linneus.

3. Found at the Cape of Good Hope by Thunberg.

4. Leaves long, narrow, ſharp. Flowers heaped in whorls at the joints.—Native of Virginia [f].

[b] Linn. ſyſt. [c] Gærtner. [d] Hort. kew. [e] Smith. [f] Gronovius.

5. In

Digitized by Google

5. In the preceding the cylindrical membranaceous ſtipule ſheaths the ſtem half way between the joints: it is not ſo in this, but as in the European ſpecies. The pedicels in the former are thicker, in this capillary. That has the flowers more in a ſpike; this has them rather in a panicle. Gronovius's ſpecimen was not red either in the ſtem or ribs[g].

The root is black or yellow on the outſide and ſaffron-coloured within. Leaves long, wide, ſcarcely acuminate. All the calycine leaflets equal[h].—Native of Virginia.

6. Curled Dock has a fuſiform yellow root. Stem angular, grooved, ſmoothiſh. Leaves waved and curled about the edge: thoſe on the ſtem almoſt linear and ſubſeſſile. Racemes not very ſpreading, but cloſe and thick together, ſomewhat leafy towards the baſe. Valves of the fruit ovate, ſubcordate, netted-veined, entire, ſubrepand but not toothed, all graniferous: the grain or bead very large, ovate, gibbous, red. Seed larger than in the ſanguineus[i].

According to Dr. Stokes, the grains, or beads as he calls them, are one or three, rarely two. Dr. Withering adds, that they are pale when young, changing to blood-red and then to brown-red; and that the valves are large, brown-red when ripe.

Mr. Woodward remarks, that the curled Dock is the peſt of Clover fields in Norfolk. Mr. Curtis has ſeen ſome in which it formed nearly half the crop.

The freſh roots bruiſed and made into an ointment or decoction cure the itch. The ſeeds have been given with advantage in the dyſentery[k].

Native of Europe, Siberia, Cochinchina, &c. in almoſt every ſoil and ſituation; as in wet meadows, by the ſides of roads, and in cultivated ground, into which it is generally introduced with dung. It flowers from june to auguſt.

The yellow root, waved leaves, and large ſeed-coverings, diſtinguiſh this ſpecies[l].

7. This is an annual plant, a ſpan high, and very much branched. Leaves petioled, even, waved, entire. The valves of the flower have three long teeth on each ſide, all covered with large pale grains.

Native of Virginia[m]. Introduced in 1773, by Chevalier Murray[n].]

8. This alſo is an annual plant, about ten inches high, ſending out a few horizontal branches towards the bottom; the leaves are about two inches long, and half an inch broad at the wideſt part. The flowers grow in whorls round the ſtalks, are very ſmall, and the hair-like beards which adhere to the covering of the ſeed, being long, obſcure the flowers, ſo that they are ſcarcely viſible to the naked eye. It grows naturally in Egypt; [and was cultivated in 1739, by Mr. Miller[o].

9. Root annual. Stem almoſt upright, a ſpan high, roundiſh, branched at the baſe. Leaves petioled, oblique. Flowers cluſtered, lateral. Calyx ſpreading. The valves of the flower all have a white ovate grain, and on each ſide two lanceolate teeth at the edge, by no means longer than the valve or briſtle-ſhaped.

Native of Egypt[p]. Cultivated in 1732, by James Sherard, M. D. at Eltham[q].

10. Root perennial. Stem angular, grooved, ſmooth, rather flexuoſe. Leaves narrow, petioled, repand. Racemes from divaricate aſcending, elongated. Flowers half-whorled, numerous, cloſe, nodding; each whorl in general ſupported by a petioled ſpreading leaflet. Valves lanceolate-oblong, entire, but ſometimes toothed at the baſe, all loaded with a very large, gibbous, red grain. Seeds ſmall. Flowers male, female and hermaphrodite; ſome of the males having twelve ſtamens[r].

Stem upright, branched. Branches upright. Leaves ſmooth, veined and keeled underneath. Petioles ſtriated, half-embracing. Stipules membranaceous, within the petioles and without the peduncles. Valve ſerrate at the lower part, oblong, bluntiſh, one graniferous[s].

[g] Linn. ſpec. [h] Gronov. and Colden. [i] Smith.
[k] Withering. [l] Curtis. [m] Linn. ſpec.
[n] Hort. kew. [o] Idem. [p] Linn. mant.
[q] Hort. kew. [r] Smith.
[s] Lyons M.S. in Relh. cant.

Native of Europe, in woods, hedges, by road ſides, in watery places and marſhes.

Dr. Withering, in the ſecond edition of his Arrangement, ſuſpected his R. paludoſus to be a variety of R. criſpus; but in his third edition he rather ſuppoſed it to be R. acutus, grown to a more than ordinary ſize. The valves, he ſays, are entire, all of them beaded, but in its younger flowering ſtate, the bead appears only upon one or two of them. They have not the ſtrongly-veined texture of R. criſpus. In the ſmallneſs of the flowers, the diſtance of the whorls, and the poſition of the floral leaves it agrees with R. acutus.

β. This variety is more twiſted, the whorls are more frequent and denſer, the leaflets under the whorls ſhorter. It is common in moiſt places[t].

11. The root of the common broad-leaved or blunt-leaved Dock runs deeply and ſtraightly into the earth, tapering, the thickneſs of the middle finger, on the outſide of a dirty brown colour, within yellowiſh; in young plants it is ſimple, in old ones divided into many branches. Stem three feet high, upright, branched to the bottom, round, ſmooth except towards the top, where it is ſlightly rugged, (with ſhort white tranſparent briſtles, *With.*) grooved, ſolid, jointed; the joints covered with obſolete withered ſtipules. Root-leaves very large, blunt, veiny underneath, the midrib often very red and downy. Stem-leaves ovate-lanceolate, pointed, ſomewhat waved, all petioled. Dr. Withering remarks, that the petioles are ſhorter than the breadth of the leaves. Racemes nearly upright, furniſhed with few leaves. Flowers in half-whorls, on capillary peduncles, ſprinkled near the top with white ſhining globules; and the pedicels ſurrounded near the baſe by an indiſtinct cartilaginous ring. Calyx-leaves boat-ſhaped, nearly as long as the petals; which are ovate, bluntiſh, ſpreading, membranous at the edges: theſe are permanent, cloſe and contain the ſeed. They are then called valves, are toothed on one edge, and one of them bears a granule. According to Dr. Smith, they are large, cordate, veined, and have awl-ſhaped teeth: the granule on the outer valve is chiefly conſpicuous, linear-oblong, and ſmall in proportion to the valves. The ſeed is larger than in the preceding ſpecies. Dr. Withering ſays, that the valves are not very evidently toothed, that the valve with the largeſt grain is outermoſt when the fruit-ſtalk bends downwards, and has the longeſt teeth; but that none of the teeth are equal in length to the diameter of the valve[u].

Native of Europe, in all ſorts of cultivated ground, among rubbiſh, in farm-yards, courts, by the ſides of ditches and paths: flowering in july and auguſt.

This Dock is ſubject to as little variety as any of the ſpecies; its broad root-leaves readily diſtinguiſh it, and theſe, though they may differ ſomewhat in ſize, vary little in ſhape: in general, the younger the plant, the more obtuſe are its radical leaves.

Of all our Engliſh Docks, this is one of the moſt common, and may be conſidered as a very pernicious weed, being very large and ſpreading, and refuſed by cattle in general[x].

Dr. Withering remarks, that fallow deer eat both this and the R. acutus with avidity, biting it cloſe to the root, ſo that it is very rare to ſee a Dock growing in a park. Dr. Stokes informs us, that the root of R. acutus is uſed by the dyers; and that it gives a great variety of ſhades, from ſtraw-colour to a pretty fine olive, and a good deep-green to cloths which have been previouſly blued. The roots of this and other ſpecies of Dock would probably anſwer the ſame purpoſe.]

Mr. Miller ſays, that the leaves were formerly much uſed for wrapping up butter; and that hence this ſpecies was commonly known by the name of Butter Dock.

12. [Stem almoſt procumbent, much branched. Branches alternate, elongated, bent back, angular, ſmooth, having a linear-lanceolate leaflet under each.

[t] Dillen. in Raii ſyn. [u] Curtis, Smith, Withering.
[x] Curtis.

Root-

Digitized by Google

Root-leaves blunt, ſinuated in the middle on both ſides, ſo as to reſemble the body of a violin: ſtem-leaves ſmall, oblong, entire. Racemes leafy. Valves deltoid, toothed, netted-veined, one more evidently graniferous than the reſt[y].

Rumex divaricatus of Linneus, figured by Tilli, *t. 3. f. 2.* and found in Italy, is in all probability not different from this. Willich having obſerved, that the ſeeds of Tilli's plant, the firſt year, had leaves that were not ſinuated; but that the ſecond, they were panduriform or viol-ſhaped[z].

13. Root perennial, conſiſting of twiſted fibres, as in many water plants. Stem angular, grooved, ſubflexuoſe, ſomewhat rugged, often red. Leaves, linear, entire, bluntiſh, flat, not waved. Racemes leafy. Whorls cloſely cluſtered, of a golden colour. All the valves have an oblong granule, with about four briſtle-ſhaped teeth on each ſide, longer than the valve[a].

Mr. Woodward remarks, that the ſtems are very leafy; Dr. Withering, that the leaves are flat and ſmooth; the four teeth of the valves like the fingers ſpread out, and the whorls of flowers golden yellow, ſo cloſely crowded together as to aſſume the appearance of leafy ſpikes:—Ray, that the ſeeds are very ſmall, lighter-coloured than in the other ſpecies; and that the leaves are paler and narrower. In the Syſtema vegetabilium the root is ſaid to be red.

Native of ſeveral parts of Europe, in marſhes, eſpecially on the ſea coaſt: but ſometimes found far inland, as at Goldington in Bedfordſhire, by Mr. Abbot.

14. Root tapering, reddiſh brown on the outſide, bright red within. Stem from two to three feet high, branched, of a reddiſh colour, grooved and ſomewhat rugged. Root-leaves very large, on long foot-ſtalks, oblong-lanceolate, a little narrowed at the baſe, blueiſh green, flattiſh, but ſlightly waved and notched on the edge: the upper leaves linear-lanceolate, almoſt veinleſs above, uſually curved upwards. Flowers moſtly yellow, placed round the ſtem in numerous thick whorls[b], which are diſtinct or even remote, and have a leaf at the baſe of each. Valves lanceolate, three-toothed at the baſe on each ſide with ſetaceous teeth, and much ſhorter than in the preceding ſpecies. Diſtinguiſhed from the preceding by its more ſlender growth, diſtant whorls, leſs golden hue, and eſpecially by the ſhortneſs of the teeth in the valves[c].

The moſt ſtriking character of the Marſh Dock, when in flower or ſeed, is the number and narrowneſs of the leaves on its branches; when viewed more cloſely, we are ſtruck with the number and length of the teeth on the edges of the ſeed-valves, which valves are frequently though not always of a yellowiſh colour, and furniſhed with remarkably large and long grains: if any doubt remain reſpecting the ſpecies, the root on being cut acroſs exhibits a beautiful red colour equal to any carmine.

Its natural ſituation is a moiſt one; as on the edges of wet ditches and rivulets, but it is not unfrequent in paſtures or drier ground. In the former it will grow to the height of three or four feet, having root-leaves a foot long and three inches broad: in the latter it ſeldom grows more than a foot high, with root-leaves about ſix inches long, and one inch or ſomewhat more broad[d].

Common about London. Obſerved in Tothill-fields by Plukenet, and in St. George's-fields by Curtis. Mr. Pitchford found it by Acle dam, Norfolk, and it grows probably in many parts of England.

It flowers in july, auguſt and ſeptember, and is one of the ſpecies leaſt noxious to the farmer. The roots are ſaid to be frequently ſold for thoſe of R. acutus[e].

Mr. Curtis ſays that he remembers once to have ſeen the leaves with red veins like thoſe of the bloody Dock: but that is not uncommon in other ſpecies growing on a dry ſoil, when in their advanced ſtate.]

15. The great Water Dock has large roots which ſtrike deep in the mud, and ſend out leaves three feet long, and four inches broad in the middle. The ſtalks riſe four feet, when the plant grows in water, but in dry land not more than two: theſe have narrow leaves among the ſpikes of flowers to the top. The flowers ſtand upon ſlender peduncles which are reflexed; they are of an herbaceous colour, and appear in june, (rather july and auguſt.) The ſeeds ripen in autumn.

[Root thick. Stem five feet high, ſtraight, grooved, ſmooth. Leaves ſomewhat glaucous, lanceolate, acute; the lower ones cordate at the baſe. Whorls approximating. Pedicels capillary, thickening at the top, nodding. Valves large, veined, ſometimes but rarely toothed a little, all having a ſmall linear granule, frequently obſolete. Seed large[f].

Root white within, black without. Leaves even at the baſe, a little toothed and waved at the edge. Petioles ſemicylindrical, thoſe of the lower leaves ſometimes fifteen inches long. Peduncles encompaſſed a little below the middle with an indiſtinct ring, in half whorls, from the alternate ſides of the ſtem and branches, ſurrounded by a ſkinny ſheath. Valves very ſlightly toothed, eſpecially towards the baſe, the teeth becoming more and more evident as the ſeed ripens. Beads or granules greeniſh-white or purpliſh[g].

Native of Europe, in ditches, pools and on the banks of ſtreams.—Called *Candocks* in Walton's Angler.

Several of the Docks had formerly ſome repute in medicine. The leaves, which manifeſt conſiderable acidity, are ſaid to poſſeſs a laxative quality, and have therefore been uſed to obviate coſtiveneſs. R. Patientia is highly ſpoken of by Allioni as ſerving this purpoſe. The roots are ſtrongly aſtringent; and thoſe of the Water Dock have been much employed both externally and internally for the cure of ſcurvy, eſpecially when the gums are ſpongy and bleed. It is alſo recommended in various cutaneous eruptions, and in viſceral obſtructions. But many phyſicians ſtill think this root does not peculiarly differ from other aſtringents, and place no faith in the great virtues aſcribed to it by Muntingius and Sir John Hill[h].

It is regarded however by Dr. Withering as a medicine of conſiderable efficacy, both externally applied as a waſh for putrid ſpongy gums, and internally in ſome ſpecies of ſcurvy. In rheumatic pains, and chronical diſeaſes, owing to obſtructed viſcera, it is ſaid to be uſeful. The powdered root is ſaid by Chevalier Murray to be one of the beſt things for cleaning the teeth.]

15. This is a low annual plant, with ſlender ſtalks, branching at the bottom, and about four inches high, the lower part having ſmall ovate ſucculent leaves; the upper part has ſmall herbaceous flowers growing in whorls, without any leaves between them. The ſeeds are ſmall, with ſharply indented reflexed covers.

[Root conical, yellow, fibrous. Stems a foot high, upright, ſlender, ſmooth. Leaves alternate, ſmooth or very ſlightly pubeſcent, quite entire; the lower ones ovate and blunt, the upper ones narrow-lanceolate or linear. Stipules very thin, large, white, ſhining, acute. Flowers in ſpikes, three together, nodding; on compreſſed pedicels, thickening gradually from the baſe to the end. Calyx-leaves ovate, reflexed. Petals toothed, nearly equal to the calyx, red[i]. The peduncle becomes thick, compreſſed, recurved, and half-channelled, when the calyx is mature. Outer valves very ſmall, reflexed, preſſed cloſe to the peduncle: inner valves much larger, briſtle-toothed, and having a flattiſh reverſed gland at the baſe. Seed ſmall, bay, ſhining[k].]

Native of Spain and Italy on moiſt ſwampy ground. [Found by Cavanilles in dry places near Mentrida, and on the heights of San Bernardino near Madrid; flowering in june: By Desfontaines on mount Atlas, and in corn fields of Barbary.—Cultivated in 1683, by Mr. James Sutherland[l].]

17. The Sorrel-tree riſes with a woody ſtalk ten or twelve feet high, covered with a ſmooth brown bark, and ſending out many branches. Leaves ſmooth, roundiſh-heart-ſhaped, two inches long, and an inch

[y] Smith. [z] Haller. [a] Smith. [b] Curtis. [c] Smith. [d] Curtis. [e] Idem.

[f] Smith. [g] Withering. [h] Woodville. [i] Cavanilles and Desfontaines. [k] Gærtner. [l] Hort. kew.

Digitized by Google

and half broad, alternate upon pretty long foot-ſtalks. The flowers come out in looſe panicles towards the end of the branches: they are of an herbaceous colour, and are ſometimes ſucceeded by triangular ſeeds with ſmooth covers; but the ſeeds rarely ripen in England.

The flowers are three-parted, not ſix-parted; and in a panicle oppoſite to a leaf[m].

Native of the Canary Iſlands. Cultivated here in 1698, by the Dutcheſs of Beaufort[n].]

18. This is an annual plant; with pretty thick ſucculent ſtalks a foot high, and dividing into many branches. Leaves round-heart-ſhaped, on very long foot-ſtalks. The flowers grow in looſe ſpikes at the end of the branches: they are herbaceous. The ſeeds have large inflated covers, with broad membranaceous borders.

[Native of Africa. Cultivated in 1656, by Mr. John Tradeſcant, junior[o].]

19. This is an annual plant; riſing a foot and half high, and dividing at top into ſeveral branches. Leaves arrow-pointed, about three inches long, the ſides of which are irregularly torn, as if they had been gnawed by inſects; they ſtand upon pretty long foot-ſtalks, and have ſmooth ſurfaces. The flowers are diſpoſed in looſe ſpikes; ſome of which have only male flowers, and others hermaphrodite. Some plants alſo have only male, and others hermaphrodite flowers. The ſeeds are incloſed in large inflated covers of a deep red colour, having membranaceous borders.

[Stem branched, ſtriated, erect, ſmooth. Leaves cordate, blunt, petioled, fleſhy, glaucous, with lucid ſpots ſcattered over them, often curled and gnawn at the edge. Stipules large, membranaceous, white, very thin. Flowers nodding, ſolitary or in pairs, panicled. Pedicels capillary. Inner valves very large, cordate, obtuſe, variegated with purple veins[p]: they are orbicular, an inch in diameter, netted, toothletted at the tip, and bifid at the baſe; which is not the caſe in R. tingitanus[q].

Native of Egypt and Barbary, in corn fields. Cultivated in 1739, by Mr. Miller[r].

20. Root perennial. Stems branched, ſtriated, procumbent. Leaves ſtiffiſh, haſtate, truncate at the baſe, unequally gnawn at the edge, often viol-ſhaped; on a petiole ſhorter by half than the leaf. Flowers in cluſtered whorls, nodding. Valves netted with purple veins[s].

Leaves ovate, acuminate, ſomewhat rugged, ſubhaſtate at the baſe and gnawn there, very rugged and generally unequal at the edge. Racemes long, with five or three flowers at each tooth of the raceme[t].

Native of Spain and Barbary: found in fields near the ſea ſhore of the latter by Desfontaines; in the former by Alſtroemer.—Cultivated in 1680, by Robert Moriſon, M. D.[u] to whom it was ſent from the neighbourhood of Algiers by Alexander Balam.

21. Root of French Sorrel hard, fibrous, perennial. Stem from a foot to eighteen inches in height, very ſlightly angular, glaucous, ſmooth, dividing into alternate ſpreading branches. Leaves cordate or haſtate, glaucous, ſmooth, ſoft, fleſhy, blunt, entire, an inch and half in length and breadth, on petioles two or three inches long, channelled within. Flowers in a ſort of whorls, forming all together ſpike-ſhaped racemes, nodding and coming out three or four together on capillary pedicels from a white ſheathlet. Valves ſubcordate, large, bright roſe-colour[x], entire, without any grains[y].

Native of Germany, Switzerland, Italy, the South of France and Barbary.—Cultivated here in 1633[z].]

The round-leaved or French Sorrel is a more grateful acid than common Sorrel, and is therefore preferred for kitchen uſe, in ſoups, &c. for which it is much cultivated by the French.

[22. Stem ſuffruticoſe. Branches round, ſtriated: internodes brown at the top, an inch long. Leaves acute, quite entire, very ſmooth, thick, veinleſs, glaucous, an inch long and more, on petioles the length of the leaves; the upper ones lanceolate. Stipules membranaceous, ſheathing; truncate. Panicle terminating. Pedicels capillary, thickened under the flower, longer than the fruit. Calyx reflexed. Valves orbicular, ſmooth, quite entire, naked[a].

Mountain Sorrel has almoſt all the leaves radical, on long petioles; kidney-ſhaped, emarginate, repand, veined, pale green. Stem naked or nearly ſo, a ſpan high, panicled. Pedicels in bundles, capillary. Valves roundiſh or ovate, emarginate, quite entire, tinged with red, without any rudiments of granules[b]. Flower four-cleft, the calyx being two-cleft, and the corolla two-petalled. Stamens ſix. Styles two[c]. Stigmas pencilled[d].

When the calyx is mature, according to Gærtner, the four leaflets are unequal, free, reflex; two larger, rounded, erect, growing cloſe to the ſeed, form a wide membranaceous margin about it. Seed ovate-acuminate, compreſſed, with a longitudinal ridge along the middle on both ſides, and of a ruſty red colour. Albumen ſhorter than the embryo, mealy, two-parted. Embryo placed in the axis of the ſeed, dividing the albumen.

Gærtner would ſeparate this from the other ſpecies, and approves of Hill's having given it the diſtinct name of *Oxyria*, in the tenth volume of his Vegetable Syſtem.

Native of the mountains of Lapland, England, Wales, Scotland, Switzerland, Sileſia, Dauphiné, Piedmont, Siberia.—Obſerved by Lawſon and Ray in Weſtmoreland and Cumberland. In Longleſdale near Buckbarrow-well, and all along the rivulet, by Mr. John Fitz-Roberts, and Mr. John Watts, apothecary in London. Mr. Miller obſerved it growing in great plenty in Yorkſhire and Weſtmoreland: Mr. Baker on walls at Tortworth: Mr. Robſon, about Keſwick. Mr. Lhwyd found it on Snowdon above Llandberis, and on Cader-Idris above Lliny-cau lake. Mr. Lightfoot, on rocks by the ſides of rivulets which run down from the highland mountains of Scotland, and in the iſlands of Rum and Skye.

24. Found at the Cape of Good Hope by Thunberg.

25. Alpine Dock, vulgarly called Monk's Rhubarb, from its having been uſed formerly for the ſame purpoſes as the true Rhubarb, has a very large perennial or biennial root, three or four inches in thickneſs, branched, woody, yellow within, running horizontally. Stem thick, ſtriated, branched, jointed: at the joints, and at the baſe of the branches and petioles are very large, membranaceous, blunt, white, tender ſheaths. Leaves at bottom large like thoſe of Rhubarb, roundiſh or ovate, blunt, very wide, wrinkled, emarginate in form of a half moon next the petiole, which is very long, thick and channelled. Stem-leaves lanceolate; all are plaited along the edge. Flowers very abundant and cloſe in long panicles. Valves large, veined, entire; but ſometimes having a tooth or two[e]. Haller obſerved male and female flowers in the ſame panicle. Its round nervoſe leaves, cordate at the baſe; its thick low ſtems; and its polygamous flowers, are characters ſufficiently diſtinctive of this ſpecies. It has the air, ſtature and ſize of Rhubarb, with nearly the ſame qualities in a leſs degree: a double doſe at leaſt muſt be taken to produce the ſame effect[f].

Native of France, Switzerland, Sileſia, Piedmont, Siberia. It was cultivated here in 1597, as appears from Gerarde's herbal[g]. Myſelf and others, ſays Gerarde, have them (this and the Patience Dock) growing for our uſe in phyſick and ſurgery.

The root of Baſtard Rhubarb, (which is his name for Alpine Dock) purgeth after the ſame manner as the Rha of Barbary, but muſt be taken in greater quantity, as witneſſeth that famous learned phyſician now living, Mr. Dr. Bright, and others who have experimented the ſame.

26. Calyx of the male flowers has the leaflets ovate, blunt, not reflexed but ſpreading. Petals a little leſs

than the calyx, one or two ſometimes wanting. The female flowers have the calyx preſſed cloſe to the germ; with leaflets keeled, acute, from upright ſpreading. The petals are much ſmaller than in the male flower. Stigmas very ſmall. Calyx and corolla both permanent and thickened to incloſe the ſeed. The calyx-leaves, when mature, have pungent ſpines [h]; whence the trivial name.

Female involucre ſuberoſe, one-leafed, pyramidal, excavated like a net, armed with three reflex pungent ſpines at the top. Seed ovate-acuminate, three-ſided above, rounded below, and having a wide umbilical ſcar at the baſe, yellow, ſhining. Albumen mealy, central. Embryo linear, white, circumferential, girting the whole albumen like a ring. Cotyledons very long, flat, incumbent. Radicle ſubcylindrical, ſhort, ſuperior [i].

It is an annual plant, native of the iſland of Candia or Crete. Cultivated in the Edinburgh garden in 1683 [k].

27. This is ſo nearly allied to R. Acetoſa, that it ſeems as if it were a mule plant derived from that: but the leaves gape more behind with hooks, and the ſtipules are longer. The root reſembles altogether that of Spiræa Filipendula. Stem upright, ſimple [l].

Native of Italy. Cultivated in 1748, by Mr. Miller [m].

28. Native of the mountains of Calabria, Tuſcany and the Levant.

29. Stem ſimple, upright, ſtriated. Leaves curled and waved, often toothed about the edge; the lower ones petioled and blunt; the middle and upper ones embracing the ſtem. It is allied to R. Acetoſa; but differs in having an upright denſe thyrſe-like panicle, and the calycine valves twice as large, and of a bright roſe colour. Perhaps it may be a variety.

Native of Barbary, in uncultivated fields [n].

30. Root perennial, running deep into the earth. Stem moſtly ſimple, erect, round, deeply ſtriated, leafy, from one to two feet high. The radical and lower ſtem-leaves on long foot-ſtalks, with a membranous cylindrical ſheathing ſtipule embracing the ſtem and torn at the top; theſe leaves are arrow-ſhaped, blunt, entire or but little waved in their ſides, but at the baſe cut into two or three large ſharpiſh teeth pointing backwards, and not, as in ſome of the ſpecies, divaricated into a right angle with the outline of the leaf. Upper leaves ſeſſile, gradually more entire, embracing, acute, a little rolled back; thoſe at the top of the ſtem only ſlightly criſped at their baſe. A compound ſort of whorled ſpike or branched panicle terminates the ſtem; its branches alternate and nearly erect. The barren flowers are on a ſeparate plant from the fertile ones: calyx and corolla ſmall, nearly ſimilar in both. Stamens very ſhort, with large yellow anthers. Styles ſhort, with large crimſon bearded ſtigmas. Valves ovate entire graniferous [o].

The root of common Sorrel is aſtringent, like moſt of this genus. The whole herb is acid, with a degree of aſtringency, not unpleaſant or unwholeſome. Taken in conſiderable quantity, it is ſaid to be of important advantage, where a refrigerant and antiſcorbutic regimen is required: its effects will be the ſame as thoſe of Oxalis or Wood Sorrel, before recited.

The leaves are eaten in ſauces and ſalads. The Laplanders uſe them to turn their milk ſour. In France Sorrel is cultivated for the uſe of the table, being introduced in ſoups, ragouts, fricaſees, &c. In ſome parts of Ireland they eat the leaves plentifully with milk, alſo with fiſh, and other alcaleſcent food. The dried root gives out a beautiful red colour when boiled. All domeſtic cattle will eat the plant [p].

Sorrel is common in meadows and paſtures, through the greater part of Europe, in almoſt all ſoils and ſituations; flowering early in june.

δ. Great Mountain Sorrel, which Haller conſiders as a ſpecies diſtinct from the common one, has according to him a woody round thick capillated root. Leaves flat, not waved; the lower ones petioled, bluntly ſagittate; the ſtem-leaves ſeſſile, embracing, about the petiole ſometimes not cut but ſtretched right out, ſometimes emarginate but not deeply: the edges flat, not wrinkled or plaited, with ſhort hooks. Sheaths truncate, white. Flowering-branches, as in the other, naked, branched. In a garden, it grows bigger, but preſerves its difference.

Native of the Alps; and found by Mr. Lhwyd near Harlech in Merionethſhire.

31. Sheep's Sorrel is leſs by half than the Common Sorrel. Root creeping, perennial. Leaves lanceolate; the lower haſtate, thoſe on the ſtem often entire. Racemes panicled. Flowers half-whorled. Valves ovate, entire, without any grains [q]. Dr. Withering remarks, that the lobes at the baſe of the leaves point upwards or horizontally, whereas in the preceding ſpecies they always point backwards: and that it is ſubject to ſome ſlight variations in the ſhape of the leaves, as repreſented in Ger. 321. 6 and 7. and Ger. emac. 398. 6.

Native of Europe, in dry, gravelly and ſandy paſtures, banks and fallows, gravel walks, where charcoal is burnt, &c. Haller obſerves, that it aſcends into the high Alps, and then becomes very ſmall.

32. This reſembles the preceding, but the leaves are attenuated at the baſe, without hooks. The inner valves of the female flowers are ciliate with very ſmall prickles.

Native of the iſland of Crete or Candia, and of Spain [r].

33. This has a tuberous root like that of S. Filipendula. Stems (in a garden) from a foot to eighteen inches in height, proſtrate, copious, branched, five-cornered, ſtriated. Leaves longer than thoſe of R. Acetoſa; of the ſame form with thoſe of the common Arum, extremely acid, purpliſh about the edge, and waved, but ſcarcely crenulate. It differs from R. ſcutatus, in having the ſtem angular, not round; and the leaves cordate-haſtate, not lanceolate-ſagittate [s].

The ſtem is very much branched, a foot high, angular, even, diffuſed. Leaves alternate, petioled, acuminate. Bractes intrafoliaceous, ferruginous. Panicle very large, divaricating, decompounded of alternate racemes. Pedicels capillaceous, the length of the fruit.—Native of the Cape [t].

Willdenow thinks it probable that R. ſpinoſus of Thunberg's prodromus may belong to this ſpecies.

Native of the mountains about Bologna.

34. Stems round fiſtular very ſmooth glaucous little branched. Leaves on long petioles triangular cordate at the baſe and ſubhaſtate ſerrulate acute ſeven-nerved veined very ſmooth. Stipules ſheathing lanceolate ſmooth oppoſite to a leaf membranaceous. Panicles terminating. Seeds with cordate very ſmooth naked entire valves, with the calyx reflexed. Cultivated in the open ground it becomes near a fathom in height, with leaves of the ſame ſize as in R. alpinus; but in a pot it is contracted and ſhrubby [u].

Native of Africa. James Bruce, Eſq. Introduced in 1775 [x].

Dr. Smith remarks, that R. arifolius of Linneus's Supplement is more certainly a native of the Alps than of Abyſſinia. He found it on Mount Cenis, in the paſtures ſurrounding the lake, below the remarkable white limeſtone rocks, before the poſt-houſe [y].

35. Root perennial. Stems a ſpan high, aſcending, even. Leaves cordate, bipinnatifid, with the ſegments diſtinct almoſt to the midrib, each pinnate or dichotomous. Stipules membranaceous diaphanous white. Raceme terminating compound, with the racemelets ſimple. Calyx blunt.—Native of Morocco [z].

36. Stems three feet high, upright, round. Leaves lanceolate, quite entire, flat, ſpreading. Flowers in ſpikes: all the valves naked, quite entire, ſmooth, unarmed.—Native of Cochinchina [a].]

PROPAGATION AND CULTURE.

All the Docks riſe eaſily from ſeeds, and if introduced into a garden, will become troubleſome weeds,

if their ſeeds be permitted to ſcatter; therefore few perſons care to propagate any of them, except for their uſe in medicine or the kitchen. The ſeeds ſhould be ſown in autumn ſoon after they are ripe. When the plants come up, thin them and keep them clean. They all delight in a moiſt rich ſoil.

16. 18. 19. Grow freely from ſeed, ſown in a bed of light earth in the ſpring, where the plants are deſigned to remain. Thin them and keep them clean.

17. The tree Sorrel is eaſily propagated by cuttings, planted during any of the ſummer months in a bed of loamy earth, and ſhaded from the ſun until they have taken root. Then take them up, and plant them in pots filled with kitchen-garden earth, placing them in the ſhade till they have taken new root; after which move them to a ſheltered ſituation, with other hardy green-houſe plants till autumn, when they muſt be removed into the green-houſe, and treated in the ſame way as other plants which only want protection from froſt.

30. Common or Meadow Sorrel is commonly cultivated in gardens, and though ſmall in the field, yet in a garden will produce fair large leaves. Sow it early in the ſpring in a ſhady moiſt border; and if the plants be afterwards removed into another ſhady border, at the diſtance of four or ſix inches ſquare, they will produce larger leaves, and continue longer.

21. Round-leaved or French Sorrel is a great runner at the root, by which means it is eaſily propagated. The roots ſhould be planted at the diſtance of two feet ſquare at leaſt. It will agree better with an open ſituation than the common ſort. If the flower-ſtems and rambling branches be cut off in the beginning of july, the roots will ſoon put out new leaves, which will be tender and much better for kitchen uſe than the older leaves; ſo that by cutting down the ſhoots of ſome plants at different times, there will always be a ſupply of young leaves.

23. As this ſort grows naturally in ſhady moiſt places, it muſt be planted on a north border in a moiſt ſoil.

25. Alpine Sorrel is full as hardy as the common ſort. The leaves having as pleaſant an acid taſte as that, being larger and more ſucculent, are better than that for kitchen uſe. This may be increaſed by ſeeds, or by parting the roots. The plants ought to be at leaſt a foot diſtant from each other, eſpecially in good ground.

[*Deſtruction of Docks.*

Mr. Curtis affirms it to be a falſe notion, that whilſt any part of a Dock-root remains, the plant will grow again; that the uſe of the Docking-iron therefore is not neceſſary, but that frequent mowing moſt certainly deſtroys it, and frequent ſpudding would probably have the ſame effect; though unleſs it be done carefully and at ſtated periods, little good is to be expected.

I do not deny that frequent mowing and ſpudding may in the end deſtroy Docks; at leaſt it will prevent one great evil, by keeping them from ſeeding. But I am certain that pulling up the young plants by hand after a ground rain, and uſing the docking-iron for old plants, or ſuch as having been mowed or ſpudded will not come up by hand, is a remedy far more effectual; and I believe upon the whole not more expenſive.

It has been mentioned before, that fallow deer keep down Docks, by biting them cloſe to the root. Mr. Marſhall mentions an inſtance of a bed of Docks being deſtroyed by ſwine or by mowing. The fact was, a large patch of Docks, as thick as they could grow upon the ground, was liable to the bite of ſwine, ſome of which will feed on Docks with avidity: what they left was repeatedly mown off, perhaps twice or thrice in a ſummer, for a ſucceſſion of years. At length they vaniſhed as by a charm, and were ſucceeded by a thick ſward of the finer graſſes.

Mr. Marſhall obſerves upon this with his uſual judgement, that perhaps neither the ſwine nor the ſcythe could in ſtrictneſs be ſaid to have killed theſe Docks; for they evidently died of old age. No vegetable is everlaſting; and the age or natural life of perennial herbs has not been attended to. We may however take it for granted, that all plants which propagate their ſpecies by ſeed alone, may be ſubdued by perſevering to prevent their ſeeding. All that we want to know from experience is their ſeveral ages, in order that we may calculate the difference between the expenſe of heading them from time to time, and that of deſtroying them at once by eradication[b].

Mr. Marſhall farther obſerves, that Docks mature their ſeeds quickly and in great abundance, but having no wings to ſcatter them at a diſtance, they fall at the foot of the plant. This renders a creeping root unneceſſary. Nature's chief care ſeems to have been to eſtabliſh the parent plant firmly in the ſoil, and to guard againſt its deſtruction. To this end it is furniſhed with a very ſtrong tap-root; which, if divided below the crown, ſends forth ſapling ſhoots from the part left in the ground, and this from almoſt any depth, provided it have head-room and the ſoil be looſe. The upper part too, if cut a few inches deep, will ſurvive the amputation. Even when inverted by the plough it will recoil, and find its way to the ſurface again.

Hence land much infeſted with Docks ſhould be gone over with the drawing or docking iron ſome time before the plough be put into it, that the tops may be removed, and the rootlets left in the ground may have time to rot before the land be ploughed. With this precaution, and with a perſon to follow the plough with a ſpadelet to grub up the bottoms, and diſengage the tops of ſuch as may have eſcaped the previous weeding, the *roots* of Docks may with great certainty be extirpated.

The *ſeeds* of Docks are to be deſtroyed by the plough, the harrow and the roller; but the intervals between the ploughings ſhould be ſhort, for if they once get themſelves eſtabliſhed in the ſoil, it is, without a favourable ſeaſon, out of the power of tillage to extirpate them.

Docks are ſometimes ſown upon the land with corn, and very frequently with clover. From corn and pulſe the ſeed may be ſeparated by the ſereen; and ſtill more effectually by the ſieve. But from clover-ſeed, the ſeeds of Docks cannot be eaſily ſeparated, being nearly of the ſame ſize and weight. Singular caution therefore ought to be had in purchaſing this ſeed. And the growers of clover ought to be aſſiduous in weeding their ſeed clover from this pernicious weed. To ſuffer a Dock which has ripened its ſeed to be thraſhed with ſeed clover, is a crime, which ought, among farmers, to be deemed unpardonable[c]. I always pull out by hand all the young plants of Dock from crops of Clover, the firſt year, and if neceſſary the ſecond year. It is eaſily done, and at no great expenſe, by women and children, after a day's rain or a heavy ſhower.

DESCRIPTION, *&c.*

This plant, when not in fruit, very much reſembles Potamogeton pectinatum or marinum, but the leaves are ſcarcely diſtich, rather alternate, very long and ſlender, pointed. The ſtipules alſo are not produced at the end, acute and bifid, but retuſe. The ſtems are filiform, and very much branched. About four flowers on a ſpike, or from one to four, though commonly two, one terminating and one ſeſſile. The ſpike emerges from the water, and therefore the peduncle or flower-ſtalk is of very different lengths, according to the depth of the water. Dr. Goodenough has remarked that it is convoluted or ſpiral, as that of Valliſneria is deſcribed to be, and relaxes or contracts as the depth of the water increaſes or diminiſhes. Anthers ſeſſile, burſting at top into two hemiſpheres. Germs ovate, after impregnation each elevated on its proper pedicel. Stamens, germs and ſeeds four in each flower [f].

Gærtner thus deſcribes the fruit. Nuts four or more, aggregate, peduncled, ovate-acuminate, corticate: rind coriaceous-membranaceous, very thin: ſhell cruſtaceous, black, one-celled, valveleſs. Seed ovate-globular, often ſlightly acuminate, pale.—Linneus marks this plant as annual, Hudſon as perennial.

Native of ſeveral parts of Europe in ſalt-water ditches. In Britain not uncommon. Ray obſerved it

[f] Smith, Withering, Robſon.

Raceme terminating hermaphrodite.

DESCRIPTIONS, &c.

1. [Roots thick, white, twining about each other, putting out frequent fibres like thoſe of Aſparagus, oblique, ſtriking deep in the ground. Stem ſuffruticoſe, tough, ſtiff, green, round, ſtriated, from eighteen inches to three feet in height, ſending out from the ſides many ſhort branches; having many leaves on them, nearly of the ſame ſhape and ſize with thoſe of Myrtle, but very ſtiff, and ending in ſharp prickly points: they are alternate, about half an inch long, and one-third of an inch broad near the baſe, ovate, quite entire, ſeſſile. From the middle of the leaf above comes out a ſingle flower, on a very ſhort pedicel, it is ſmall and yellowiſh green or purpliſh; when it firſt appears, it is the ſize and ſhape of a ſmall pin's head; when expanded compoſed of three outer widiſh calyx-leaves, and three inner narrower like rays, ending in a narrow point. The three laſt ſome conſider as petals; and Mr. Stackhouſe found a male flower fallen from the plant, which had only three leaves correſponding with thoſe of the calyx. Mr. Woodward remarks, that the flower does not properly grow out of the leaf, but on a pedicel from the boſom of the leaf, which is immerſed beneath the outer coat, whence it may with eaſe be diſſected. The female flowers are ſucceeded by berries, which are red, bigger than thoſe of Aſparagus and almoſt as large as ſome Cherries, of a ſweetiſh taſte; having two large orange-coloured

Digitized by Google

ſeeds in each, gibbous on one ſide, flat on the other, and extremely hard. The flowers come out in march and april, and the ſeeds ripen in winter[z].]

The green ſhoots are cut, bound into bundles and ſold to the butchers for ſweeping their blocks, whence its common name in Engliſh.

[It is very frequently made into beſoms in Italy. The huckſters there alſo place the boughs round their bacon and cheeſe to defend them from the mice[b]. From Virgil's account of the Ruſcus, it ſeems as if it was uſed in Italy to tie up the vines. But the ſecond ſort was more adapted to that purpoſe. Or perhaps it was Miller's flexuoſus, obſerved in Italy by Micheli; which is five feet high with very pliant branches.]

The young ſhoots in the ſpring are ſometimes gathered and eaten by the poor like thoſe of Aſparagus; and the branches with the ripe fruit on them were formerly ſtuck up in ſand, with the ſtalks of male Peony, and wild Iris or Gladwyn, full of their ripe ſeeds, which all together made a ſhow in rooms during winter. Planted under trees or ſhrubs the Ruſcus will ſpread into large clumps, and as it retains the leaves all winter, will have a good effect.

[The root has a bitteriſh taſte, and was formerly much recommended as an aperient and diuretic in dropſies, urinary obſtructions and nephritic caſes. Dioſcorides ſpeaks highly of its deobſtruent and diuretic powers, under the name of μυρσινη αγρια; Riverius relates a caſe of dropſy ſucceſsfully treated by a decoction of the roots. Bauhin and others give ſtrong caſes of its effects in dropſy; but at preſent this plant is very rarely, if ever, employed in medicine[i]. It may however hereafter take its turn with Hemlock, Foxglove, Mezereum, &c.

Native of Europe, but not in the northern parts. It is ſaid that it will not bear the winters of Sweden. Native alſo of Aſia and Africa. In England it is not uncommon in woods, thickets and hedges. Mr. Ray remarked it at Black Notley in Eſſex, where he lived. Bobart, in the woods of Berkſhire and Oxfordſhire. Mr. Crowe, in Hethel woods near Norwich. Mr. Woodward, near Loweſtoft, in Suffolk. Dr. Withering, in the New Foreſt, near Stony Croſs. Mr. Ray, at Angleſey Abbey in Cambridgeſhire. Dr. Sibthorp, between Caverſham and Maple Durham in Oxfordſhire. Blackſtone, in Perry wood, near Feverſham in Kent. In Ray's ſynopſis it is ſaid to be common on heaths about Woolwich. Mr. Blackſtone has it in his catalogue of plants about Harefield in Middleſex. It has been found on Hampſtead heath by Gerarde. I have obſerved it in Norwood, Surry. Butcher's Broom does not ſeem to have been found in Scotland, or in the very northern counties of England. It is known by the names of Knee-holly, Knee-holm or Knee-hulver, pricking or wild Myrtle, and prickly Pettigree. In French it is called le Houx frelon, petit Houx, Buis piquant, and Fragon piquant.

β. Dillenius has figured two ſingle leaves, which are larger than in the common ſort, and ſeem to be a variety only of that.

Mr. Fairbairne, gardener to the company of Apothecaries at Chelſea, preſented to the Linnean Society, in 1796, a living ſpecimen of a Ruſcus, which though long cultivated there, had been overlooked as a variety of the aculeatus. It has this ſpecific character given by the Preſident: leaves elliptic acute at both ends mucronate-pungent above floriferous naked, branches looſe. From this laſt circumſtance Dr. Smith named it *Ruſcus laxus*[k].]

2. The roots of this have large knotty heads, with long thick fibres like thoſe of the preceding ſort; from which ariſe many tough limber ſtalks near two feet high. Leaves ſtiff, ovate-oblong ending in points, more than two inches long and almoſt one broad, placed alternately. Flowers produced on the under ſurface of the leaves near the middle, ſitting cloſe to the midrib; they are ſmall and herbaceous. The female flowers are ſucceeded by ſmall red berries about the ſize of thoſe of Juniper.

[z] Ray hiſt. Withering. [b] Idem. [i] Woodville. [k] Linn. tranſ. 3. 334.

[Stems ſuffruticoſe, green, ſimple, very ſlightly ſtriated. Leaves perennial, coriaceous, ſhining, quite entire; the lower ones in whorls. Petioles very ſhort, accompanied by an acute ſcale at the baſe. Flowers glomerate, from the middle and generally from the lower ſurface of the leaves. Pedicels filiform, unequal, one-flowered. Calycine ſegments linear, white, reflexed. Stamens ſix: filaments united into a cylinder. The female has ſix barren ſtamens. Berry red, ſhining, pendulous. Seed commonly one, horny, white, round; with two others that are abortive[l].

Native of Italy and Africa. It flowers in may and june; and was cultivated in 1683, by Mr. James Sutherland[m].

Parkinſon, who makes two of this, ſays that he had one by means of Dr. Flud, and the other from his good friend Maſter John Tradeſcant.

β. Dillenius figures and deſcribes a plant which he regards as intermediate between this and the next ſpecies.]

3. Root like the preceding. Stems about ten inches high. Leaves lanceolate, about three inches long, and one inch broad in the middle, drawing to a point at both ends, and having ſeveral longitudinal veins running from the foot-ſtalk to the point: they are moſtly alternate, but ſometimes oppoſite. On the middle of the upper ſurface comes forth a ſmall leaf of the ſame ſhape; and at the ſame point, from the boſom of the ſmall leaves, come out the flowers, which are of a pale yellow colour. The berries are almoſt as large as thoſe of the firſt ſort; they are red and ripen in winter.

[According to Scopoli, the ſtem is a cubit in height, ſimple, grooved, of the ſame colour with the leaf. Leaves oblong, nerved; the lower in whorls; the upper alternate. Flowers two or three, from a ſcaly neſt. Peduncles longer than the flowers, but ſhorter than the fruit, covered by a lanceolate leaflet. Berry red, ovate. Seeds one or two, bony, hemiſpherical.

Desfontaines regards it as a variety of the preceding, differing only in having narrower leaves, and the flowers emerging from the middle of the leaf under a leaflet.

Native of Italy, Idria, Hungary, Africa about Algiers.—It flowers in april and may; and was cultivated by Gerarde in 1597[n].]

4. This ſends out pliant ſtalks which riſe ſeven or eight feet high, and have ſeveral ſhort branches proceeding from their ſides. Leaves ſtiff, about two inches long, and one inch broad towards their baſe, where they are rounded to the foot-ſtalk, but they end in acute points; many longitudinal veins run from the foot-ſtalk to the point. The flowers are produced in cluſters on the edges of the leaves, and are white. Berries yellowiſh red, not ſo large as thoſe of the firſt ſort.

[Stems two or three cubits in length, green, the ſize of a finger or more at bottom, from the middle upwards the ſize of a ſtraw, whence, at the diſtance of about two inches from each other, ſpring branches from a hand to a ſpan in length, having ſix, ſeven or eight leaves on them, placed alternately, except in the terminating branch, whereon they are oppoſite: the leaves are evergreen, ſmooth and even, ſhining, contracted towards the baſe, and pointed at the end, marked with ſlender parallel veins: all together having the appearance of a pinnate leaf. Some of theſe leaves are entire; others, eſpecially the upper ones, in their wider part have a ſinus, next to which from the lower part of the leaf, in the month of may, ſpring greeniſh globules in a ball, which in five or ſix weeks expand into ſo many flowers, larger than in the other ſpecies, divided down to the baſe into ſix equal ſegments, naked, on very ſhort pedicels, pale at firſt, but turning yellower as they advance. Berry round, firſt green, then yellowiſh, and finally red. Seed large, globular, horny.

This differs from the other ſpecies in having androgynous flowers divided into ſix equal ſegments to the

[l] Desfontaines. [m] Hort. kew. [n] Idem.

bottom,

Digitized by Google

bottom, but falling off in one piece, and ariſing from the edge, and not the diſk of the leaf[o].

Native of the Canary Iſlands. Cultivated in 1713, in the Royal Garden at Hampton Court. It flowers moſt part of the ſummer[p].]

5. Roots like thoſe of the other ſpecies. Stalks ſlender and much more pliable: they riſe about four feet high, and ſend out many ſide branches. Leaves oblong, acute-pointed, about two inches long, and one-third of an inch broad, rounded at the baſe, ſmooth, of a lucid green, placed alternately, and ſeſſile. Flowers in long bunches at the end of the branches, of an herbaceous yellow colour. Berries like thoſe of the firſt ſort, but ſmaller; ripening in winter: [—ſuperior, globular, fleſhy, ſmooth, red, with a round coriaceous white diſk at the baſe, three-celled. In each cell one ſeed, but frequently one only in the whole berry, ovate-globular, obſcurely angular, at the top ſlightly acuminate, and marked with a lateral umbilicus near the tip, below blunt, pale yellow or the colour of honey. The umbilicus of the ſeed is inſerted into a ſmall ſcar in the upper part of the partitions. It frequently happens that one ſeed only ripens, and then the berry becomes one-celled. Haller has given an inſtance of this in hort. goetting. Sometimes the berry is two-celled: but the natural number of cells is three, and that is the moſt common. The embryo of the ſeed is one-lobed, nearly cylindric, but with one end more turgid and exterior; the other attenuated, ſlightly compreſſed and interior: it ſcarcely exceeds one-third of the albumen in length, and is placed in the lower part of it, oppoſite to the umbilicus[q].

Native of Portugal, (Linneus and Miller ſay, the Iſlands of the Archipelago.) It was cultivated in 1739, in the botanic garden at Chelſea[r]. Mr. Ray ſays (1686) that he ſaw it in the Royal Garden at Paris. Could it be above half a century in travelling from Paris to England?]

The Alexandrian Bay, (or Alexandrian Laurel, as it is now generally called) is ſuppoſed to be the plant, with which the ancients crowned their victors. The ſtalks, being very pliable, might eaſily anſwer this purpoſe; and the leaves having a great reſemblance to thoſe which are repreſented on the ancient buſts.

[The ſame ſtory was told of the ſecond ſpecies, before this was ſo well known[s]. But there is no foundation for the opinion that either of them graced the heads of ancient heroes. See *Laurus nobilis*.

The Alexandrian Laurel is a beautiful elegant ſhrub, and ſhould appear in the front of all ornamental plantations.]

Mr. Miller has three other ſpecies:—

1. Ruſcus trifoliatus, n. 5. with ovate-acuminate leaves placed by threes, and flowers on their upper ſides. This he ſays, is a native of Zante, and ſome other Greek iſlands. The ſtalks are about two feet high, ſlender, pliable, with leaves about two inches long and an inch broad rounded at both ends, terminating in acute points, having ſeveral longitudinal diverging veins running from the footſtalk to the point, and placed by threes round the ſtalk. The flowers grow on the under ſide of the leaves, faſtened to the midrib; they are naked, and have pretty long footſtalks, and their ſegments are very narrow. There is little doubt of this being a variety of the ſecond ſpecies. Mr. Miller contradicts himſelf in the ſpecific character and the deſcription.

2. Ruſcus flexuoſus, n. 6. with ovate-acuminate leaves, bearing flowers on their upper ſides, and flexible ſtalks.—R. latifolius major fructu folio innaſcente, of Micheli.

It is a native of Italy, where it was diſcovered by Micheli. The roots are much longer than thoſe of the firſt ſort; the ſtalks riſe near five feet high, are very pliant, and ſend out ſeveral ſide branches their whole length. The leaves are ſtiff, an inch long, and half an inch broad. The flowers are produced on the upper ſurface of the leaves ſitting cloſe to the midrib, ſmall and herbaceous. The berries are ſmaller than thoſe of the firſt ſort, and of a pale red when ripe. This can be nothing more than a variety of R. aculeatus. May it not be the R. laxus of Dr. Smith?

3. Ruſcus fruteſcens, n. 8. with a ſhrubby branching ſtalk, lanceolate ſtiff leaves, and flowers growing upon foot-ſtalks terminating the branches.—R. latifolius fruteſcens, floribus racemoſis rubris. *Houſt. MSS.*

This was diſcovered by Dr. Houſtoun at Carthagena in New Spain. It riſes with ſhrubby ſtalks eight or ten feet high, and dividing into many branches. Leaves three inches long, and one inch broad in the middle, ending in acute points: ſome are in whorls, others oppoſite. The flowers are produced in looſe bunches at the end of the branches, on ſlender foot-ſtalks; they are ſmall, of a red colour, and ſhaped like thoſe of the firſt ſort.

PROPAGATION AND CULTURE.

1. 2. 3. 5. All theſe ſorts being very hardy, and thriving in almoſt any ſoil or ſituation, are very proper for planting round the verges of cloſe woods, or under large trees in wilderneſs quarters; and as they are always green, they make a good appearance in winter, after the deciduous trees have caſt their leaves. They are eaſily increaſed by parting their roots in autumn; but when this is performed, if they are divided into ſmall parts, it will weaken them ſo much, that they will make little figure, until they have had two or three years growth. They may alſo be propagated by the ſeeds, but this being a very tedious method, is ſeldom practiſed.

4. This being tender muſt be planted in pots filled with freſh earth, and in winter removed into the green-houſe; but it ſhould be placed where it may have free air in mild weather, for it only requires to be ſcreened from froſt, and in ſummer muſt be ſet abroad with other hardy green-houſe plants. With this management the plants will ſend forth ſtems ſix or eight feet high, furniſhed with leaves from bottom to top, and in june will be cloſely ſet with flowers upon their edges, which make a very beautiful and odd appearance, and render it worthy of a place in every good collection of plants. This is alſo propagated by parting the roots as the former, which ſhould not be done very often; becauſe, if the roots are not permitted to remain ſome time to get ſtrength, they will produce but weak ſhoots, and very few flowers; and in the ſtrength of their ſhoots and number of flowers, the greateſt beauty of theſe plants conſiſt. This ſort may alſo be propagated from ſeeds; but theſe commonly lie in the ground a year before the plants come up, ſo ſhould be ſown in pots filled with freſh earth, and placed under a hot-bed frame in winter, to ſcreen the ſeeds from the froſt, and the following ſpring the plants will appear.

SPECIES.

1. Ruſſelia ſarmentoſa.
Jacqu. amer. 178. *pict.* 171.

DESCRIPTION, *&c.*

Stems ſhrubby, four-cornered, wandlike, ſmooth, very long and weak, numerous, ſupported on neighbouring ſhrubs three or four feet in height, and then bending down again. Leaves ovate, ſerrate, acute, ſomewhat hirſute on the upper ſurface and at the edge, ſmooth on the under ſurface, on very ſhort petioles, oppoſite, an inch long, and placed at two or three inches diſtance from each other. Peduncles axillary, oppoſite, three-flowered or two-flowered, only half the length of the leaves, in the direction of the ſtem; the pedicels reflexed after the flowers fall. At the baſe of each pedicel a lanceolate bracte. Flowers handſome, of a fine red colour, but without ſcent, almoſt an inch over.

Found by Jacquin about Havana, in cloſe woods and coppices[t].

Juſſieu remarks that the fruit requires more accurate examination.

DESCRIPTIONS, *&c.*

1. Root woody, branched. Stems fruteſcent, covered with a rugged, gray, ſtriated bark, eighteen inches high and more. Branches, eſpecially the young ones, ſmooth and pale green. Leaves glaucous, pulpy, dotted, divided like the umbellate plants, doubly pinnate, or more properly what Linneus calls ſuperdecompound. Leaflets obovate, ſeſſile; the lower ones ſmalleſt; the end one commonly trifid with the middle lobe much larger than the reſt. Flowers in a branching corymb on ſubdivided peduncles. Haller calls it a ſemiumbelled raceme; and Linneus a panicle, the firſt branches of which are two-parted, with the reſt of the flowers alternate. The flower that firſt opens, and

Digitized by Google

and is below the others on a very ſhort pedicel, has a five-parted perianth, and a five-petalled corolla, with ten ſtamens; this Linneus calls the primary flower, and takes the character of the claſs from it. The other flowers have a four-parted perianth, and a four-petalled corolla, with eight ſtamens. In all the calyx is ſmall; the petals concave or boat-ſhaped, ſpreading out wide from each other almoſt horizontally, and of a yellow colour with a tinge of green in the middle; the ſtamens alternately merged in the hollow of each petal and ſpreading ſtraight out in the middle between them. Germ very large dark green.

Gærtner thus deſcribes the fruit. It is a ſubglobular capſule, with the ſurface ſcrobicular dotted, the upper half dividing into five lobes in the primary flower, and into four lobes in the reſt, within divided into as many cells, and opening into as many parts between the lobes. Receptacles five or four, ovate, fleſhy, excavated, faſtened to each internal angle of the cells. Seeds about ſix in each cell, oblong, angular-reniform, rugged with very minute wrinkles, aſh-coloured.

Native of the South of Europe, and flowering from june to ſeptember. It appears from Turner, our oldeſt botanical writer, that it was cultivated in England in 1562[u]. But its medical qualities having been rated ſo high, there can be little doubt of our having had Rue in our gardens ſome centuries earlier.

Rue was anciently alſo named in Engliſh *Herb Grace* or *Herb of Grace*; if I am not miſtaken, it is to this day called *Ave-Grace* in Suſſex, in alluſion doubtleſs to *Ave Maria gratiâ plena:* and it is remarkable that Mary in hebrew ſignifies bitter. Warburton ſays that Rue had its name *Herb of Grace* from its having been uſed in exorciſms. But although this plant be celebrated as a cure for almoſt every diſeaſe, as a counterpoiſon, and as good againſt the peſtilence, yet I do not find this excellence of it recorded. When Ophelia, in Shakſpeare's Hamlet, ſays to the Queen—"there's Rue for *you*, and here's ſome for *me:* we may call it Herb of Grace o' ſundays:"—the fair moraliſt has no reference to this plant being uſed in exorciſms performed in churches on ſundays; but means only, that the queen may with peculiar propriety, on ſundays, when ſhe ſolicits pardon for that crime which ſhe has ſo much occaſion to rue and repent of, call her Rue *herb of grace*. It was indeed the common name for Rue in Shakſpeare's time: and Greene, in his Quip for an upſtart Courtier, has this paſſage:—"ſome of them ſmiled and ſaid, *Rue* was called *Herbegrace*, which though they ſcorned in their youth, they might wear in their age, and that it was never too late to ſay *miſerere*[x]."

The Gardener in Richard II. ſays of the Queen:

"Here did ſhe drop a tear; here in this place,
"I'll ſet a bank of Rue, ſour *herb of grace*:
"Rue even for ruth, here ſhortly ſhall be ſeen,
"In the remembrance of a weeping queen."

Here the gardener plays upon the name, and might miſlead an etymologiſt who knew no better. He might with more truth have called Rue bitter than ſour; and he whimſically enough makes it take the place of Roſemary; which was the emblem of *remembrance*, as Rue was of *grace*. Thus Perdita, in the Winter's Tale—

——— "Reverend ſirs,
"For you there's Roſemary and Rue; theſe keep
"Seeming and ſavour all the winter long:
"Grace and remembrance be to you both."

They are both evergreens, retaining their appearance and taſte during the whole year, and therefore are proper emblems of remembrance and grace.

Rue ſeems to have been uſed formerly in noſegays; for the Clown in All's well that ends well, having ſaid of the Counteſs, "ſhe was the ſweet-marjoram of the ſalad, or rather the herb of grace." Lafeu replies; "they are not ſalad-herbs, you knave, they are noſe-herbs." Upon which the Clown, in character, remarks; "I am no great Nebuchadnezzar, ſir, I have not much ſkill in graſs:" thus punning upon the name of Grace, as the Gardener did upon the other name of Rue.

Rue was much uſed by the ancients. Hippocrates commends it as a reſolvent and diuretic, and attributes to it the power of reſiſting contagion and poiſons; which is now very little credited, though ſo highly extolled by Boerhaave. It is doubtleſs a powerful ſtimulant, and may be conſidered, like other medicines of the fetid kind, as having attenuating, deobſtruent and antiſpaſmodic powers: and as peculiarly adapted to phlegmatic habits, or weak and hyſterical conſtitutions, ſuffering from retarded or obſtructed ſecretions. *Ruta* is directed by the London College in the form of an extract, and it is alſo an ingredient in *Pulvis e myrrha compoſitus*. By ſome it is employed in the way of tea[y].

β. The deſcription given above is chiefly from the wild plant. The garden ſhrub differs little from this except in ſize. In hot climates it is ſaid to become a tree.]

Mr. Miller diſtinguiſhes two garden ſpecies: the firſt, which he calls Ruta hortenſis, riſing to the height of five or ſix feet. The ſecond, Ruta altera, is only three or four feet high, and has narrower leaves. The flowers grow in longer and looſer bunches. The ſeed-veſſel is ſmaller. This being hardier than the firſt, has almoſt ſupplanted it in the gardens about London.

2. The lower leaves are compoſed of ſeveral parts, which are joined to the midrib in the ſame manner as other branching winged leaves, and have linear leaflets ſtanding without order. Stalks from two to three feet high, branching out from the bottom, and garniſhed with leaves divided into five parts, and thoſe at the top into three, which are as ſmall and narrow as the bottom leaves; they are of a gray colour, but not ſo fetid as thoſe of the preceding. The flowers grow at the end of the branches in looſe ſpikes, which are generally reflexed. The petals are yellow. The ſeed-veſſels are ſmall, and filled with angular black ſeeds.

[It is now generally agreed that this which Mr. Miller diſtinguiſhed under the name of R. ſylveſtris, is a diſtinct ſpecies. Haller ſays it is very different; having a branched ſtem, two feet high, the leaves much more finely divided, with the laſt ſegments linear and very ſharp.

According to Villars, the leaves are decompoſed, and the leaflets cylindric, very narrow, a little reſembling thoſe of *Seſeli glaucum*. Stem ſtraight and ſimple; the flowers though alternate, are turned to one ſide, and borne on branches which ſpring nearly from the ſame point, ſo that they appear to be in an umbel. The petals are entire, a little concave, with the border membranous and entire.

It differs, ſays Desfontaines, from R. graveolens, in having the leaves multifariouſly decompounded, with the leaflets very narrow and linear. The plant is corroſive, and has a very ſtrong ſmell.

Native of the South of Europe, and Barbary. It flowers in auguſt and ſeptember; and was cultivated by Mr. Miller in 1739[z].

3. This is very like R. graveolens, and is its offſpring. The firſt flowers are five-cleft, and the others four-cleft, as in that. The petals are concave with a waved margin, as in R. graveolens; but the ſtem is loftier. The petals are ciliate at the edge[a].

Leaves thick, blunt, ſingly-winged or ternate. Petals hollowed like the bowl of a ſpoon, with great flatted hairs like the eye-laſhes round them. They ſmell inſupportably ſtrong. It ſeems only to be a variety of R. graveolens[b].

Stem three feet high, upright, round, very much branched. Leaves ſuperdecompound, oblong-ovate, ſmalliſh, cinereous, ſmooth, ſtrong-ſmelling. Flowers in a terminating panicle. Segments of the calyx four, acute, ſpreading. Petals four, ovate, concave, ciliate, yellow. Pores of the nectary ten. Stamens eight. Capſule four-lobed, rugged, four-celled[c].

[u] Hort. kew.
[x] Malone and Henley in Steevens's Shakſpeare.
[y] Woodville. [z] Hort. kew. [a] Linn. mant.
[b] Villars. [c] Loureiro.

β. This variety differs in having the claws of the petals longer, and the lobes of the capſule approximating, not diſtant [d].]

Mr. Miller deſcribes R. chalepenſis as having ſtrong ſhrubby ſtalks about three feet high, dividing into many branches; leaves larger than thoſe of the common ſort, with a ſtronger odour; the flowers diſpoſed almoſt in form of an umbel at the end of the branches, having five concave yellow petals whoſe borders are ſet with fine hairs, and ten ſtamens of equal length with the petals; the ſeed-veſſels much larger than thoſe of the common ſort.

[Native of Africa: of Arabia, according to Linneus; of Dauphiné, according to Villars, of Aleppo and the Cape of Good Hope, according to Miller, cultivated in China and Cochinchina, according to Loureiro. In 1722, it was cultivated in the botanic garden at Chelſea. It flowers from june to ſeptember [e].

Linneus having obſerved that the Rue moves one of its ſtamens every day to the piſtil, Dr. Smith examined this ſpecies, which differs very little from the common Rue, and found many of the ſtamens in the poſition which he deſcribes, holding their anthers over the ſtigma; while thoſe which had not yet come to the ſtigma were lying back upon the petals, as well as thoſe which, having already performed their office, had returned to their original ſituation. Trying with a quill to ſtimulate the ſtamens, he found them all quite devoid of irritability: they are ſtout, ſtrong, conical bodies, and cannot, without breaking, be forced out of the poſition in which they happen to be. The ſame phænomenon has been obſerved in ſeveral other flowers; but it is no where more ſtriking, or more eaſily examined than in the Rue. Hence Dr. Smith concludes, that theſe plants are endued with a kind of ſpontaneous motion [f]. This is not a very philoſophical concluſion. To a ſimilar effect we are taught to aſſign the ſame cauſe: and becauſe we cannot excite the irritability, it does not therefore follow that the ſubject is not irritable.

4. Stem as in the other ſpecies. Leaves pinnate, compoſed of three pairs with an odd leaflet: the lateral leaflets oppoſite, linear, entire or crenulate, dotted; the odd leaflet ſubovate, ſerrate [g].—Native of the Canary Iſlands by Maſſon. Introduced in 1780. It flowers in march [h].]

5. The ſtalk riſes ſingly from the root, is about a foot high, and herbaceous. Leaves alternate, narrow. The ſtalk branches at the top in form of an umbel, ſuſtaining many yellow flowers, compoſed of five entire plane petals, having no hairs on their borders. It ſeems to be a plant of ſhort duration.

[This ſpecies was firſt diſcovered by Micheli near Arqua, not far from Padua. He conſidered it as a diſtinct genus, becauſe it has five flat naked petals. It was cultivated by Mr. Miller in 1768.]

6. This riſes with ſeveral ſingle ſtalks from the root near a foot and half high. Leaves three quarters of an inch long, and one eighth of an inch broad, of a yellowiſh green colour, alternate, ſeſſile; at their baſe one or two very ſmall, but of the ſame ſhape and colour. Flowers in ſmall cluſters at the end of the ſtalks: petals five, oblong, yellow. Stamens ten, equal in length to the petals, terminated by awl-ſhaped anthers.

[The lateral branches of the panicle, bifid, three-flowered, with the middle flower ſeſſile. Petals five, ſeſſile, entire, ovate. Filaments hairy at the baſe, cloſely confining the receptacle pricked with melliferous pores. The pericarp has raiſed dots [i].

Stems herbaceous, ſmooth, round, upright, often many from the ſame head, ſimple or ſcarcely branched. Leaves ſcattered, ſmooth, quite entire, ſpatuled-lanceolate, blunt, thickiſh, running down the petiole: the lower ones ſmaller. Flowers in terminating corymbs. Bractes linear-lanceolate, leafy. Calyx five-toothed. Petals entire, concave, ovate, blunt. Filaments ciliate at the baſe. Germ ſurrounded by five villoſe tubercles [k].

[d] Linn. mant. [e] Hort. kew.
[f] Philoſ. tranſ. vol. 78. for 1788. p. 162. [g] Linn. ſuppl.
[h] Hort. kew. [i] Linn. ſpec. [k] Desfontaines.

Native of Spain, and Tunis. Cultivated by Mr. Miller in 1759.

β. Buxbaum's plant is not different from that which grows in Spain [l].

7. Stem a ſpan high, moſt branched at bottom: branches hairy, round. Leaves alternate, entire, ſeſſile; the upper ones ſmaller. Calyx very ſmall, hairy, with blunt teeth. Petals entire, ſeſſile, ſlightly concave, yellowiſh. Filament widening and lanuginous at the baſe, ſhorter than the petals. Anthers four-grooved. Germ five-lobed, hairy. Style club-ſhaped, twice as long as the ſtamens. Capſule hairy, retuſe, hollow-dotted. The fructification is very ſeldom four-parted [m].

The flowers are as ſmall again as in the preceding ſpecies, and the petals are more clawed.—Native of Media, and of Syria near Damaſcus [n].]

PROPAGATION AND CULTURE.

All theſe plants may be propagated either by ſowing their ſeeds, or by planting ſlips or cuttings; both of which may be done in the ſpring. The manner of propagating them from cuttings being the ſame as for Lavender, Stæchas, and other hardy aromatic plants, need not be here repeated; and if they are propagated by ſeeds, there needs no farther care but to dig a bed of freſh earth in the ſpring, making it level; then to ſow the ſeed thereon, and rake the ground ſmooth; after which, keep the beds clear from weeds until the plants are come up about two inches high, when they ſhould be tranſplanted out into freſh beds, where they may remain for uſe.

The Aleppo Rue, and the wild Rue are tenderer than the common ſort, ſo require ſhelter in winter; but the Aleppo Rue will endure our ordinary winters very well in the open air, eſpecially if it be planted on a dry ſoil.

All the ſorts of Rue will live much longer, and are leſs liable to be injured by froſt in winter, when they grow in a poor, dry, rubbiſhy ſoil, than in good ground; for in rich moiſt land the plants grow very vigorouſly in ſummer, and are ſo replete with moiſture, that a ſmall froſt will kill their tender ſhoots; whereas in poor dry ground, or when they grow upon old walls, their growth will not be great, but their ſhoots will be hard and compact, and thus more able to reſiſt the cold.

The firſt ſort was formerly uſed to plant for edgings on the ſides of borders; but it was by no means proper for this uſe, for the plants ſhoot ſo vigorouſly, that there is no keeping them within the bounds of an edging; beſides when they are kept cloſely ſheered, they appear to be very ragged and ſtumpy, and their roots ſpread ſo far as to exhauſt the goodneſs of the ſoil, ſo that the other plants are deprived of their nouriſhment, which has cauſed it to be wholly neglected for this purpoſe; ſo that at preſent it is chiefly cultivated for medicinal uſe, or to furniſh the balconies for the citizens in the ſpring, eſpecially that with a variegated leaf.

5. This is propagated by ſeeds, ſown in autumn, ſoon after they are ripe. The plants will come up the following ſpring. Whereas when the ſeeds are ſown in the ſpring, the plants ſeldom riſe the ſame year. On poor ground or among rubbiſh, in a warm ſituation, it will live in the open air without covering; but in rich ground it is frequently killed in winter.

6. This alſo will live through the winter in the open air, on a poor dry ſoil, and will perfect ſeeds the ſecond year; but as it is of ſhort duration, young plants ſhould be raiſed annually, to keep up a ſucceſſion.

DESCRIPTIONS, *&c.*

1. This is a paraſitical underſhrub, with round ſmooth branches. Leaves alternate, entire, without nerves or veins, thick, ſhining, very ſmooth, pale green, three or four inches long, on ſhort plano-convex petioles. Racemes at the ends of the branches, ſimple, a foot long, nearly upright, many-flowered; the common peduncle round, thick, ſomewhat ſucculent, ſmooth; flowers ſcattered, alternate, ſmall, on pedicels three lines in length. Calyx-leaves ovate, ſmooth, incumbent: under the calyx two oppoſite leaflets, preſſed to it, ſmall, ovate, between which is a ſeſſile, obovate, acute, thick, deflexed, concavo-convex bracte, bigger than the lateral leaflets, dotted with red. Petals purple, deciduous. Filaments five, (or according to Jacquin ſix or ſeven) the length of the petals, into which they are inſerted at the baſe; they are widiſh, upright, purple. Style none, or very ſhort and thick. Stigma plano-convex, four or five-rayed. The fruit appears to be a berry; and as far as can be judged from the upright germ, two-celled and many-ſeeded [o].

Native of Martinico, in the vaſt moiſt woods, flowering in april [p].

2. Stem ſarmentoſe, round; with long, divaricate, flexile, declining, round, fragile branches. Leaves alternate, acuminate at the baſe, emarginate at the top, mucronate in the middle with a minute toothlet; ſmooth on both ſides, thickiſh, fleſhy; on ſhort round petioles channelled above. Racemes terminating; ſimple, long, many-flowered. Flowers alternate, ſomewhat remote from each other, large; on round fleſhy pedicels, an inch in length. Calyx-leaves five, (according to Aublet, five or ſix,) roundiſh, concave: two lateral leaflets at the baſe of the calyx oppoſite, longer than the calyx, lanceolate, blunt, concave, diverging, bent down, red; the third above cylindric-club-ſhaped, tubular, ſcarlet. Petals oblong, deciduous, yellow. Filaments yellow, wider at the baſe. Anthers brown. Germ oval, five-cornered. Style ſcarcely any. Stigma fleſhy, flat, five-rayed.

Native of the woods in Guiana, by the banks of the river Gallion. Found there by Aublet [q].

DESCRIPTION, *&c.*

This is a tree with handſome flowers, and round aſh-coloured boughs, covered with a very fine nap towards the end. Leaves alternate, a ſpan long, elliptic, (or oblong) acuminate, ſmooth on both ſides, obliquely nerved, quite entire: the midrib underneath mealy; the nerves raiſed, and between theſe very fine, frequent, ſimple, tranſverſe veins. Petiole very ſhort, channelled above. Stipules awl-ſhaped, hoary, a little longer than the petiole, deciduous. Peduncles axillary, very ſhort, ſolitary or ſometimes two together, and then one is abortive, one-flowered. Calycine leaflets an inch and half long. Berry double the ſize of a Walnut. Seeds a little bigger than Coriander.

It ſeems to be allied to Laetia; but differs in having the calyx permanent; in the nectary; in having the anthers awl-ſhaped not round; four ſtigmas; the berries ſubglobular, not ſcored with lines or having a cartilaginous membrane within; finally in the ſeeds not being angular. The leaves reſemble very much thoſe of Caraipa longifolia of Aublet; but the fruit is totally different. It was found in the Iſland of Trinidad by Ryan, to whom the genus is conſecrated [r].

GENERIC CHARACTER.

CAL. *Glume* two-valved, one-flowered: *valves* oblong-lanceolate, acuminate, erect, concave, equal, awnleſs, ſurrounded with a long lanugo at the baſe.

COR. two-valved, ſhorter, ſharpiſh, very tender. *Nectary* two-leaved, very ſmall.

STAM. *Filaments* three, capillary, the length of the corolla. *Anthers* ſomewhat oblong.

PIST. *Germ* oblong. *Styles* two, feathered. *Stigmas* plumoſe.

PER. none. *Corolla* inveſts the ſeed.

SEED ſingle, oblong.

OBS. *In* Saccharum *the wool is without the calyx*; *in* Arundo *it is within it.*

ESSENTIAL CHARACTER.

Cal. two-valved, involucred with a long lanugo. *Cor.* two-valved.

SPECIES.

[1. Saccharum Teneriffæ. *Teneriffe Sugar-cane.*
Lin. ſyſt. 103. *Willd.* 1. 320. *ſuppl.* 106.
Leaves awl-ſhaped flat, flowers panicled awnleſs, hairy involucre none, calyx very villoſe.

2. Saccharum ſpontaneum. *Wild Sugar-cane.*
Lin. ſyſt. ed. 13. 88. 14. 103. *Reich.* 1. 147. *Willd.* 1. 321. *mant.* 183. *ſuppl.* 106. *Gærtn. fruct.* 2. 11. *Lour. cochinch.* 52. *ed. Willd.* 65.
S. biflorum. *Forſk. deſcr.* 16. *n.* 50.
Kerpa. *Rheed. mal.* 12. 85. *t.* 46.
Leaves convolute; panicle effuſed, ſpikes capillary ſimple, flowers remote involucred geminate, one of them pedunculed.

3. Saccharum japonicum. *Japan Sugar-cane.*
Lin. ſpec. ed. Willd. 321. *Lin. tranſ.* 2. 328.
S. polydactylon. *Thunb. jap.* 42. (excl. ſynon.)
Fuku vulgo Tſikuſits. *Kæmpf. amæn.* 5. 899.
Boo vulgo Obanna. *Kæmpf. amæn.* 5. 899.
Racemes in bundles; petals ciliate, the outer ones awned.]

4. Saccharum officinarum. *Common Sugar-cane.*
Lin. ſpec. 79. *Reich.* 1. 147. *Willd.* 1. 321. *hort. cliff.* 26. *mat. med.* 46. *Woodv. med. bot.* 535. *t.* 196. *Brown. jam.* 229. *Lour. cochinch.* 52. *ed. Willd.* 66. *Plenck, ic.* 40.

Gr. tom. creticum ſpicatum, ſpica purpurea. *Scheuch. gram.* 57.
Panicle ſpiked cylindric, peduncles one-flowered, flowers awnleſs two-ſtamened, leaves flat, joints bearded.

11. Saccharum Thunbergii. *Thunberg's Sugar-cane.*
Lin. ſpec. ed. Willd. 323. *Retz. obſ.* 5. 17.
Panicle ſpiked cylindric, peduncles one-flowered, flowers awnleſs two-ſtamened, leaves convolute, joints ſmooth.

DESCRIPTIONS, &c.

1. This graſs is a foot high and more. Culm jointed, with the joints approximating leafed. Leaves ſhort, ſtraight, very ſmooth. Panicle of a middling ſize, like that of *Holcus lanatus*. Calycine valves ovate, ferruginous, hirſute, with white ſpreading hairs. Anthers yellow. It differs from the other ſpecies in having the calyx hirſute, whereas in the others it is naked. It has not the involucre of the floſcules, which in the others conſiſts of long ſtraight villoſe hairs. The glumes of this are ovate, and not ſubulate as in the next ſpecies.

Native of the iſland of Teneriffe; where it was found by Maſſon[a].

2. Culm twelve feet high, but not at all arboreſcent, the thickneſs of a gooſe quill, even, covered by the ſheaths of the leaves, hollow. Leaves two feet long, convolute at the ſides, even, of the breadth common in graſs. Panicle large, ſimple, conſiſting of capillary, very ſimple and long ſpikes, nearly erect; in which the florets are at the teeth of the rachis, within a white wool longer than they, in pairs; one ſeſſile, the other peduncled ſurrounded by its proper wool. Corolla one-valved.

Native of Malabar, in watery places; obſerved by Koenig[c]. In the Society Iſles. Loureiro ſays it is frequent in Cochinchina in marſhes and wet places; that it creeps at the root, and thus diffuſes itſelf far and wide, eſpecially near rivers.

Gærtner ſays, that he could not diſcover the one-valved corolla, which Linneus attributes to it, in his ſpecimens.

3. Culm fruteſcent, round, ſmooth, ſimple, a fathom in height. Leaves linear-enſiform, gradually drawing to a point at the end, ſerrate, ſmooth, ſtriated; the midrib thick, keeled, entire. Flowers panicled: panicle patulous, thinly and little branched; but the racemes capillary, flexuoſe, ſmooth, very long, even a ſpan in length. Pedicels in pairs alternately, recurved, one-flowered, ſmooth, one a line in length, the other ſhorter by half. Calyx ſmooth: glumes equal, acute. One valve of the corolla concealed within one of the glumes of the calyx, awnleſs; the other awned: the awn a little twiſted, twice as long as the calyx. Down at the outer baſe of the calyx, hairy, upright, unequal, white, a litttle longer than the calyx.—Native of Japan; flowering in july.

There is a variety of this, which is only three feet high; with a ſimple ſpreading panicle, conſiſting of long ſimple racemes in bundles, wandlike or ſubfaſtigiate, angular, ſmooth, a ſpan long. Valves of the

S A C

corolla equal, very thin, ciliate, one of them awned: the awn on the longer-pedicelled floret ſhorter, on the ſhorter-pedicelled floret twice as long as the calyx, twiſted, always from the tip of the corolla. All the florets have both ſtamens and piſtils, and therefore there is no polygamy in this ſpecies.

Native of Japan: that in water near the ſhore oppoſite to Nagaſaki, flowering in july; this about Nagaſaki, flowering in ſeptember [u].]

4. The root of the Sugar-cane is jointed, like that of other ſorts of Cane or Reed. From this ariſe four, five, or more ſhoots, proportionable to the age or ſtrength of the root, eight or ten feet high, according to the goodneſs of the ground. In ſome moiſt rich ſoils, Canes have been meaſured near twenty feet long; but theſe are not near ſo good as thoſe of middling growth; abounding in juice, but having little of the eſſential ſalt. The Canes are jointed, and theſe joints are more or leſs diſtant, in proportion to the ſoil. A leaf is placed at each joint, and the baſe of it embraces the ſtalk to the next joint above its inſertion, before it expands; from hence to the point it is three or four feet in length, according to the vigour of the plant; there is a deep whitiſh furrow or hollowed midrib, which is broad and prominent, on the under ſide; the edges are thin and armed with ſmall ſharp teeth, which are ſcarcely to be diſcerned by the naked eye, but will cut the ſkin of a tender hand, if it be drawn along it. The flowers are produced in panicles at the top of the ſtalks; they are from two to three feet long, and are compoſed of many ſpikes nine or ten inches in length, which are again ſubdivided into ſmaller ſpikes; theſe have long down incloſing the flowers, ſo as to hide them from ſight. The ſeed is oblong-pointed, and ripens in the valves of the flower.

[Loureiro thus deſcribes the Sugar-cane of Cochinchina.—Culm ten feet high, ſimple, round, ſolid, juicy, thick, jointed, perennial. Leaves lanceolate-linear, flat, rough, ſtriated, acuminate, embracing, four feet long, and three inches wide. Flowers terminating, in a large, diffuſed panicle, compoſed of long, ſimple ſpikes, with a long down or lanugo, or rather very long, flexuoſe, very fine hairs, inſtead of a calyx, there being none in this ſpecies.

He mentions three remarkable varieties, differing in the culm, not in the flower. 1. *White Sugar-cane*; with the culm long, white, of a middling ſize, very ſweet, the knots diſtant. — 2. *Red Sugar-cane*; with the culm ſhort, thicker, red, very juicy, the knots approximate.—3. *Elephantine Sugar-cane*; with the culm very thick, red, long, leſs ſweet, the knots approximate.

Sir George Staunton deſcribes the Sugar-cane of China, as being longer jointed than that of the Weſt Indies, with an equal diameter; the internodes of the former being generally ſix inches in length, whereas thoſe of the latter ſeldom exceed four. Doubtleſs in a plant ſo extenſively cultivated as the Sugar-cane, the varieties muſt be numerous.

The French have introduced into their Weſt Indian iſlands plants from the Eaſt Indies, and thence they have been introduced into ſome of the Engliſh iſlands. Sir John Laforey planted them in Antigua, and proved their ſuperiority over the old Canes of the Weſt Indies. He gives this account of theſe, and the Canes from Otaheite.—One brought from the iſland of Bourbon, reported by the French to be the growth of the coaſt of Malabar. Another from Batavia. A third from the iſland of Otaheite. The two firſt are much alike, both in appearance and growth: but the laſt is much larger than the common Sugar-cane of the Weſt Indies, the joints of ſome plants meaſuring eight or nine inches in length, and ſix in circumference. The colour of the canes, and of the leaves is alſo different. They are ripe enough to grind at the age of ten months, and are ſaid to make the fineſt Sugar. They appear to ſtand dry weather better; and are not liable to be attacked by that deſtructive inſect called the *borer*.—The Batavian Canes are a deep purple on the outſide; they grow ſhort-jointed, and ſmall in circumference: but bunch exceedingly, and vegetate ſo quick, that they ſpring up in one third of the time that common canes do [x].

Native both of the Eaſt and Weſt Indies, China, Cochinchina, Africa, and the iſlands of the South Sea.

It has been aſſerted that the Sugar-cane is not indigenous of America; but that it migrated through the Europeans from Sicily and Spain to Madeira and the Canary iſlands; and afterwards to the Weſt Indian iſlands and to Mexico, Peru and Brazil. On the diſcovery of the weſtern hemiſphere however the Sugar-cane was found on the continent, and in ſome of the iſlands; but the art of making Sugar, it is ſaid, never was practiſed by the native inhabitants of the iſlands or South America. Of this there may be ſome doubt with reſpect to Mexico.

Thus far is certain, that before the diſcovery of the Weſt Indies in 1492, by the Spaniards; before the diſcovery of the Eaſt Indies by the Portugueze in 1497; and before the diſcovery of the Brazils by the ſame nation in 1500; abundance of Sugar was made in the iſlands of Sicily, Crete, Rhodes and Cyprus. The Sugar-cane is ſuppoſed to have been brought to theſe iſlands originally from India by the Saracens; and thence tranſplanted into ſome parts of Italy; and to Spain from Africa, by the Moors. In Spain the Sugar-cane was firſt planted in Valencia, and afterwards in Granada and Murcia. Sugar was formerly produced in great quantity in theſe ſouthern provinces, and ſome is ſtill made in the two latter.

From Valencia the cultivation and manufacture of Sugar were carried by the Spaniards to the Canary iſlands in the 15th century: but prior to this period, the Portugueze, in 1420, carried the cane, and the manufacture from Sicily to Madeira. Hence the culture of the Sugar-cane, and the art of making Sugar, were extended to the Weſt Indian iſlands and the Brazils. The Canary iſlands were conquered by the Spaniards between 1400 and 1495.

But the Sugar-cane itſelf was found growing near the mouth of the Miſſiſippi, when Europeans firſt went to that part of America. Father Hennepin, who was there in 1680, ſays that the banks of that river were full of Canes, from thirty leagues below Maroa down to the ſea.

Francis Ximenes, Hernandes and Piſo all affirm that the Sugar-cane grows ſpontaneouſly near the Rio della Plata.

Jean de Lery, who went to Rio Janeiro in Brazil in 1556, ſays he found every where near that river a great quantity of Sugar-canes.

According to Labat, the firſt French ſettlers in St. Chriſtopher, Martinique and Guadaloupe found Sugar-canes wild in different parts of thoſe iſlands.

America therefore poſſeſſed the plant, but had not found out the art of cultivating it, and manufacturing it into Sugar, except in Mexico and Peru.

In 1506, according to Antonio Herrera, the Cane was carried from the Canaries to the iſland of Hiſpaniola or St. Domingo, by Aguillon or Aquilon, an inhabitant of la Vega. Bachiller Velloſa and Pedro Atiença were the firſt who extracted Sugar from them; and they yielded ſo well, that in a ſhort time there were on the iſland forty water and horſe mills. But in the iſland of St. Thomas under the line, on the coaſt of Africa, Sugar was made much earlier than in the Weſt Indies. It was diſcovered in 1405, and Dapper ſays that the Portugueze had ſixty-one ſugar works there, before the Dutch deſtroyed them in the year 1610.

The ſame nation firſt eſtabliſhed ſugar works in the Brazils in 1580. The Dutch had acquired ſeven of the fourteen captainſhips there, but being diſpoſſeſſed of them; the remainder, about ſix or ſeven hundred in number, in 1655 carried the art of planting the Cane and making Sugar in a proper manner to the Weſt Indies.

Sugar indeed was made at Barbadoes in 1643, by the Engliſh. But when Ligon arrived there in 1647, they were but bare Muſcovadoes; ſo moiſt and full of melaſſes, and ſo ill cured, as to be hardly worth ſending

[u] Thunberg.

[x] Edward's hiſt. preſ. Moſeley, p. 23.

Digitized by Google

to England. In 1650, when he left the iſland, they were much improved, but not ſo good as thoſe of Brazil.

The Engliſh made Sugar in the iſland of St. Chriſtopher in 1643, and the French ſoon after. In 1648, the latter made it at Guadaloupe. The Engliſh did not make it in Jamaica till 1664. On the reduction of the iſland by them in 1656, the Spaniards had only three ſmall plantations on it[f].

Our Gerarde ſays; "Myſelfe did plant ſome ſhootes "thereof in my garden, and ſome in Flaunders did "the like: but the coldnes of our Clymate made an "end of mine, and I think the Flemmings will have "the like profit of their labour." This was in 1597, when we had no ſtoves for exotic plants in Europe.

Though the Weſt Indies now chiefly ſupplies Europe with Sugar, yet it was firſt brought to it from Arabia and the Eaſt Indies, or rather from the latter through the former. Dioſcorides, Pliny, Galen and Paulus Ægineta all deſcribe it as white like ſalt, brittle between the teeth, and ſweet like honey. This ſubſtance has been commonly taken for the *Tabaxir*, which has been noticed under *Arundo Bambos*, but that was not ſweet; and there is little doubt of its being cryſtallized Sugar.

There have ever been, ſince our knowledge of the Eaſt, two ſorts of Sugar made there; raw or muſcovado Sugar, and Sugar-candy; the firſt uſed only for culinary purpoſes, the ſecond for every other purpoſe of diet, luxury and exportation. The former is, and we have reaſon to ſuppoſe ever has been made in Bengal and other diſtricts of the Eaſt Indies: but China and Cochinchina ſeem to be the only countries in the Eaſt where the bright tranſparent Sugar-candy is made in perfection. It is exported from China to every part of India, even where abundance of Sugar is made: and Du Halde ſays, that it conſtitutes a great trade to Japan[g]. Father Loureiro informs us that Sugar is cultivated to a much greater extent in Cochinchina than in China; and that cryſtallized Sugar is exported from that country in great quantities. He thus deſcribes the method of making it. The raw Sugar being purified, by putting it into conical earthen veſſels, with a thin ſtratum of moiſt clay on the top, and diſcharging the impurities through a ſmall hole in the bottom; this whitened, or as we call it, clayed Sugar is diſſolved in water over a fire, and boiled to the conſiſtence of a thick ſyrup; it is then expoſed in a cool place during the night, with ſome ſlender rods cut from the Indian reed ſpread over it; the ſyrup, as it is condenſed by the nocturnal cold, adheres to theſe rods, and is formed into beautiful cryſtals.

None of the Eaſtern nations much eſteem any other Sugar than this, which probably has its name from two Indian words *Shukur* and *Khand*, both ſignifying Sugar in general. They uſe it in tea, coffee and all other beverages: and this may account for the art of refining this article into loaf-ſugar having been little practiſed in the Eaſt. The manufacture of loaf-ſugar is ſaid to be the diſcovery of a Venetian at the end of the 15th or beginning of the 16th century. It was firſt practiſed in England in 1544.

The Venetians, before the year 1148, imported conſiderable quantities of Sugar from India by the Red Sea, and alſo from Egypt. Sugar was likewiſe made before that time in Sicily. With the produce of this iſland, and the Sugar imported from India and Egypt, the Venetians carried on a great traffic, and ſupplied all the markets of Europe with this commodity. Indeed the Venetian hiſtory informs us, that even prior to 991, the Venetians, then forcing their commerce with the Saracens into Syria and Egypt, brought back thence in return, not only Rice, Dates, Sena, Caſſia, Flax, &c. but alſo Sugar[h].

Sugar, when firſt introduced, was uſed only medicinally. Pliny leaves no room for doubt on this point. Even in Arabia, in Avicenna's time, though Sugar was an article of commerce from the Eaſt, there is no record of its being uſed for dietetic or culinary purpoſes, for ſeveral centuries afterwards.

[f] Moſeley, 14 to 40. [g] Ib. 61 to 66. [h] Ib. 67 to 71.

Sugar was employed originally to render unpleaſant and nauſeating medicines grateful to the ſick: and in pharmacy, in ſyrups, electuaries, confections and conſerves.

Actuarius was the firſt phyſician who ſubſtituted Sugar for Honey in medicinal compoſitions. Dr. Moſeley ſuppoſes him to have written in the year 1000; but others place him three centuries later.

Dioſcorides, who is the firſt that mentions Sugar by name, is alſo the firſt who ſpeaks of its medicinal qualities.

Galen recommends it among the articles to be uſed for the regimen of the ſick in fevers. And Paulus Ægineta adviſes a piece of the Indian ſalt, which in appearance reſembles common ſalt, but in ſweetneſs, honey; to be kept in the mouth to moiſten it in fevers.

The Arabians recommend Sugar for the ſame purpoſe, for aſſuaging thirſt and opening the bowels.

Among the moderns Simon Paulli, Theophilus Garencieres, Dr. Thomas Willis, and Mr. Ray, condemned the uſe of Sugar, as injurious to the lungs, as having contributed to the increaſe of conſumption and ſcurvy in England.

Others, as Baptiſta Porta, Pomet, Lemery, Geoffroy, Boerhaave, were much in favour of Sugar, and particularly Dr. Frederick Slare, whoſe unqualified praiſes of it may be oppoſed to the no leſs unqualified cenſures of Garencieres and his followers. No man has been more laviſh in the praiſes of Sugar as a dietetic than Dr. Benjamin Moſeley[b].

As a medicine, Sugar cannot be conſidered as poſſeſſing much power. Dr. Cullen claſſes it with the attenuants; and Bergius ſtates it to be ſaponaceous, edulcorant, relaxing, pectoral, vulnerary, antiſeptic, nutritive. In catarrhal affections both this and Honey are frequently employed: it has been advantageouſly uſed in calculous complaints; and from its known power in preſerving animal and vegetable ſubſtances from putrefaction, it has been given with a view to its antiſeptic effects. Sugar-candy or Barley-ſugar, by diſſolving ſlowly in the mouth, are well ſuited to relieve tickling coughs and hoarſeneſs. The uſe of Sugar in various medicinal compoſitions is too obvious to require being particularly pointed out[c].

Two centuries have ſcarcely elapſed, ſince it can be properly ſaid, that Sugar has become an ingredient in the popular diet of Europe. There are now very few perſons, who do not mix more or leſs of it in their daily food; excepting the poor remote inhabitants of the interior and northern parts.

When Sugar was firſt introduced into England, it is difficult to aſcertain: though it was in uſe in 1466, yet it was chiefly confined to feaſts and to medicine, until it was brought from the Brazils, about 1580, to Portugal, and imported from thence.

The quantity conſumed in England has always kept increaſing; though the whole conſumption for near a century ſubſequent to this period was inconſiderable.

The importation in 1700 amounted to 481,425 hundred weight, or 48,142 hogſheads, at ten hundred weight each. The price then was 32s. the hundred weight.

The average importation into England and Scotland for 1787, 1788, 1789, and 1790, amounted annually to 1,952,262 hundred weight.

The annual exportation during this period was 296,996 hundred weight, which leaves the annual conſumption in England and Scotland 1,655,266 hundred weight, or 118,233 hogſheads, of fourteen hundred weight each. Thus we find 185,389,792 pounds of Sugar are annually conſumed in England and Scotland. But the latter does not conſume more than 12,000 hogſheads: the conſumption therefore of England only is 166,573,344 pounds. Now taking the population of England at eight millions, each individual, at an average, has about twenty pounds of Sugar in the year. Ireland conſumes annually 20,000 hogſheads[d].

The

Digitized by Google

The Sugar in common uſe, is prepared from the expreſſed juice of the cane, boiled with quick lime, or common vegetable alkali, to imbibe the ſuperfluous acid. The boiling is repeated in ſmaller and ſmaller veſſels, during which it is often neceſſary to ſcum the impurities, and employ additional alkali; when the juice acquires a due conſiſtence, it is ſuffered to cool in a proper veſſel, and the ſaccharine matter concretes into a cryſtallized maſs. This, after being ſeparated from the melaſſes, is ſold under the name of brown or moiſt Sugar. This may be purified in conical moulds, by ſpreading on the upper broad ſurface ſome moiſt clay, which gradually transfuſes its moiſture through the maſs of Sugar, and carries with it a conſiderable part of the remaining treacly matter: it is then called clayed Sugar. Loaf Sugar is prepared in this country from the other Sugar boiled in water; lime water and bullock's blood or eggs, commonly both, being added to it, in order to clarify it, by incorporating with the oily and mucilaginous parts, and forming a ſcum, which is carefully taken off. After ſufficient clarification it is ſtrained through a woollen cloth, and boiled again until it becomes of a proper conſiſtence; it is then poured into a refrigeratory, and when duly cooled, into conical clay moulds, perforated at the apex, which is placed downwards; at firſt this aperture is ſtopped up, but as the Sugar concretes it is opened, in order that the ſyrup or melaſſes may drain off. By this draining, the cone of Sugar ſhrinks at the baſe below the edges of the mould, which, to render the loaf ſtill whiter, is filled up with moiſt clay cloſely applied to the baſe of the Sugar-cone: laſtly, the cone is placed upon its baſe, taken out of the mould, wrapped in paper, and dried or baked in a cloſe oven [e].

Sugar is manifeſtly a neutral ſaline ſubſtance, conſiſting of a peculiar acid, united to a ſmall quantity of alkali and much oily matter. It cryſtallizes in hexaedral truncate priſms: and affords by diſtillation an acid phlegm, with a few drops of empyreumatic oil; the reſidue is a ſpongy light coal, which contains a ſmall quantity of vegetable alkali.

Diſſolved in water it undergoes fermentation, and acquires firſt a vinous, then an acetous flavour. The vinous liquor diſtilled yields a ſtrong ardent ſpirit, commonly known under the name of Rum.

Bergman ſeparated the acid of Sugar, and exhibited it in a cryſtalline form. But this acid is found in a variety of other ſubſtances, not only vegetable, as gums, reſins, galls, ſtarch, ſalt of ſorrel, lemon juice, ſpirit of wine, &c. but animal; Berthollet having obtained from wool more than half its weight of this acid.

Sugar, or the ſaccharine matter, may be extracted from moſt vegetables, particularly the maple, the birch, beet, parſnep, grapes, &c. but the Sugar-cane affords it in larger quantities, and more readily than any other [f].

5. Height from three to four feet. Culm round, jointed, ſmooth. Leaves widiſh, keeled, linear, acute, entire, ſmooth: ſheaths ſmooth, except at the neck, which is hairy. Panicle terminating. Spikes near a foot long, faſtigiate, looſiſh, in a ſort of whorl: rachis filiform, ſlightly flexuoſe. Spikelets on very ſhort pedicels, remote, moſtly directed one way, ſmall. Calycine valves flattiſh, narrower than the corolla, but longer and more tender, pellucid; the outer a little longer than the inner. Down or lanugo three times as long as the valves, whitiſh and ſhining, inſerted at the baſe into the ſides of the valves, in bundles. Valves of the corolla equal, ovate, acute, one convex the other flat, yellowiſh, ſmooth.—It very much reſembles S. polydactylon of Thunberg; (S. japonicum) but that is diſtinct from this, in having the ſpikes in bundles, the glumes of the corolla ciliate, the outer ones awned.

Native of the Iſland of St. Chriſtopher; where it was found by Maſſon [g].

6. Culms as high as ten feet, thick, half void, leafy. Leaves wide, in whorls, approximating to the ſtem. Panicle two feet long, contracted, with a four-cornered rachis. Peduncles, in whorls, three-ſided, jointed: Of the two florets which grow together, the ſeſſile one is hermaphrodite, and that which is pedicelled is often male. Calyx-glumes equal, with the wool three times as long as they. Corolla moſt frequently three-valved; the valves hyaline, leſs than the calyx; one longer, acuminate. Nectary, two or three very tender hyaline ſcalelets. The male flowers have frequently only two ſtamens. Styles bearded, blackiſh.

Native of the Eaſt Indies, whence it was ſent by Koenig. It is cultivated by hedges and on the banks of pools near Tranquebar. The Tamules call it *Pee-Carumbo*, or Devil's Sugar. The entire culms are often uſed for the lower covering of roofs, but they are a harbour for ſerpents, lizards, and other vermin. *Koenig* [h].

7. This is ſo like to *S. arundinaceum*, that it might very eaſily be taken for the ſame; but it differs in having the corollas two-valved, all the florets hermaphrodite, and the ſtigmas of a yellowiſh brown colour.

Native of Bengal, whence it was ſent by Koenig [i].

8. Culm a foot high, ſimple, aſcending. Leaves ſmooth, ſhort. Whitiſh hairs at the edge of the ſheath. Panicle the ſize of that in *Holcus lanatus*: branches covered with white ſcattered hairs. Florets fenced with white ſhining villoſe hairs. Calyx ſmooth. Corolla awned.—Native of Guinea [k].

9. Culm the thickneſs of the finger or thumb, upright, ſmooth. Leaves ſmooth, as large as thoſe of Arundo Donax, ſerrate, with the midrib white. Flowers very numerous, in a long looſe panicle, which is ſilky, ſilvery and much branched. Calyx-glumes narrow, nearly equal, villoſe on the outſide, with ſilvery hairs longer than the flowers. One glume of the corolla longer than the other, with a ſhort briſtle-ſhaped awn. It is a very beautiful plant; and the Arabs make tobacco-pipes of the ſtraw [l].

Native of Italy, Provence, and Mount Atlas, on the banks of ſtreams.

10. Roots long, ſlender, twiſted, white. Culm often branched at the baſe. Leaves glaucous, ſmooth, hard, convolute. Spike cylindrical, ſilky, long, denſe, branched. Calyx ſurrounded with numerous, long, ſnowy briſtles. Corolla very ſhort. Anthers and ſtyles violet-coloured. It keeps together driving ſands [m].

Culm ſlender, from a foot to a foot and half in height, with white, erect, bearded hairs at the joints. Root-leaves many, flat: ſtem-leaves few, ſheathing. The whole panicle appears quite white with wool, three times as long as the florets. Stamens two, with yellow anthers. Stigmas villoſe, brown.

Koenig ſent this ſpecies under the name of S. diandrum, and Thunberg from Japan, by the name of S. ſpicatum [n]: but it is not S. ſpicatum of Linneus.

Native of the South of France, Italy, Sicily, Candia, Smyrna, Barbary, and the Eaſt Indies.

11. This is a very tall Graſs; with the panicle more contracted and twice as long as in the preceding, with the wool rather yellowiſh. Joints of the culm quite naked. Leaves rigid. Flowers twice as big. Corolla only half the ſize of the calyx, thin, of a very ſhining white colour.

Native of the Eaſt Indies: gathered by Thunberg [o].]

PROPAGATION AND CULTURE.

The Sugar Cane is preſerved by way of curioſity in ſeveral gardens in England, but being too tender to thrive here, unleſs it is preſerved in a warm ſtove, it cannot be brought to any great perfection. I have ſeen ſome of the plants growing which were ſeven or eight feet high, and at the bottom as large as a common walking cane, but they have not produced their panicles of flowers here.

It is here propagated by ſlips taken from the ſides of the older plants; thoſe which grow near the root and

[e] Woodville. [f] Moſeley, 108 to 125. [g] Swartz. [h] Retz. [i] Idem. [k] Willdenow. [l] Desfontaines. [m] Idem. [n] Retzius. [o] Idem.

have

have fibres to them, will moſt certainly grow; ſo that when the ſhoots are produced at ſome diſtance from the ground, the earth ſhould be raiſed about them, that they may put out fibres before they are ſeparated from the mother plant. Theſe ſlips ſhould be planted in pots filled with rich kitchen-garden earth, and plunged into a moderate hot-bed of tanners bark, being careful to ſhade them from the ſun until they have taken new root, after which they muſt be treated in the ſame way as other tender plants from the ſame countries. They muſt be conſtantly kept plunged in the tan-bed in the ſtove; and as their roots increaſe in ſize, the plants ſhould from time to time be ſhifted into larger pots; but this muſt be done with caution, for if they are over-potted they will not thrive: they will require to have water frequently in warm weather, but it muſt not be given them in too great plenty, eſpecially in cold weather. As the leaves of the plants decay, they ſhould be cleared from about the ſtalks; for if theſe are left to dry upon them, it will greatly retard their growth. The ſtove in which this plant is placed, ſhould be kept in winter to the ſame temperature of heat as for the Pine-apple, and in hot weather there ſhould be plenty of free air admitted to the plants, otherwiſe they will not thrive.

I ſhall here ſubjoin ſome account of the method of propagating and cultivating the Sugar Cane in America, with ſome obſervations and experiments which have been made by a few curious perſons in the Britiſh Iſlands, and ſhall propoſe ſome farther trials to be there made, in the culture and management of this uſeful plant, which are founded upon the experience I have had in the culture of ſome plants which are ſimilar in their growth with the Sugar Cane.

The land which is moſt proper for the growth of Sugar Canes, is ſuch as has a ſufficient depth of ſoil, and is not too moiſt and ſtrong, but rather light and eaſy to work; for although ſtrong moiſt ground will produce much taller and bigger Canes than the other, yet the quantity of Sugar will be much leſs, not near ſo good, and will require a greater quantity of fuel, and a longer time to boil, before the Sugar can be made; which is alſo the caſe with all freſh land, where there has not been any Canes growing before; therefore many of the moſt expert planters burn their land when it is firſt cleared for planting of Canes, to abate its fertility; but if when land is firſt cleared of the wood, and the roots of bad weeds, it is ſown with Indigo, which ſuch freſh ground will produce much better than the old, or ſuch as has been long cultivated, there may be two or three crops of this taken, which will prepare the land for the Sugar Canes, without being at the trouble of burning it; but the growing of Indigo has been ſo little practiſed in the Britiſh Iſlands of America for many years paſt, as to be eſteemed unworthy the notice of a Sugar planter; whereas if they would ſometimes change their crops to other ſpecies, they would ſoon find an advantage in the growth, not only of their Canes, but alſo of their other crops: however, the uſual practice is to continue the Canes always upon the ſame land as long as it will produce them, without changing the ſpecies, or allowing the ground a fallow to reſt and recover itſelf. By this method there are ſome plantations ſo much exhauſted, as that the crop of Sugar will ſcarce defray the expenſe of culture.

Another thing ſhould always be obſerved in the planting of freſh land with Canes, which is to allow them more room than is generally done; for as the ground is ſtrong, ſo there will be a greater number of ſhoots come out from each plant, and not having room to ſpread at bottom, they will draw each other up to a great height, and be full of watery juice, the ſun and external air being excluded from the Canes by the multiplicity of leaves, which are both abſolutely neceſſary to ripen and prepare the ſalts during the growth of the Canes.

If the ground is proper for the Sugar Canes, and they are planted at a good diſtance from each other, and the land is carefully managed, the ſame plantation may be continued about twenty years without replanting, and produce good crops the whole time; whereas in the common method, they are generally replanted in ſix or ſeven years, and in ſome poor land they are continued but two or three.

The Canes are in thoſe warm countries propagated by cuttings or joints, of proper lengths; theſe are from fifteen to twenty inches long, in proportion to the nearneſs of their joints or eyes. Theſe cuttings are generally taken from the tops of the Canes, juſt below the leaves; but if they were choſen from the lower part of the Canes, where they are leſs ſucculent and better ripened, they would not produce ſo luxuriant ſhoots, and their juice would be leſs crude, and contain a greater quantity of ſalts, which will be obtained by leſs boiling than thoſe Canes in the cloſe manner they are commonly planted; this is well known to the judicious to be the caſe, in moſt kinds of vegetables; and it is by thus carefully propagating all kinds of eſculent plants, either in the choice of the beſt ſeeds or cuttings, that moſt of the kinds have been ſo greatly improved of late years.

The diſtance which the Canes are uſually allowed in planting, is from three to four feet, row from row, and the hills are about two feet aſunder in the rows; in each of theſe hills they plant from four to ſeven or eight cuttings, which is a very great fault, and is the cauſe of moſt of their blights ſo much complained of lately; for if all theſe grow, which is often the caſe, they rob each other of their nouriſhment; and if a dry ſeaſon happens before they have acquired ſtrength, they are very ſoon ſtinted in their growth, and are then attacked by inſects, which ſpread and multiply ſo greatly, as to cover a whole plantation in a little time: when this happens, the Canes are ſeldom good after, ſo that it will be the better way to root them entirely up when they are ſo greatly injured, for they very rarely recover this diſorder; for although the inſects are not the cauſe of the diſeaſe, yet they confirm it, and cauſe it to ſpread.

Therefore, if inſtead of planting ſo many, there was but one good cutting planted in each hill, or to prevent miſcarriage, two at moſt; and if both ſucceeded, the weakeſt were drawn out ſoon after they had taken root, it would be found of great ſervice to prevent theſe blights; and although the number of Canes will not be near ſo great from the ſame ſpace of ground, yet the quantity of Sugar will be full as much, and will require little more than a fourth part of fuel to boil it.

I have been aſſured by two of the moſt ſenſible and judicious planters of Sugar in America, that they have made ſome experiments of the horſe-hoeing culture for their Canes, which anſwered much beyond their expectations; one of thoſe gentlemen told me, he planted one acre in the middle of a large piece of Canes, in rows at five feet aſunder, and the hills were two feet and a half diſtant, and but one cutting to each hill. The ground between the rows was from time to time ſtirred with the horſe plough, to deſtroy the weeds and earth the plants; with this culture the Canes were double the ſize of thoſe in the ſame piece, which were cultivated in the uſual way; and when the Canes were cut, thoſe which had been thus planted and managed were ground and boiled ſeparately; the produce of Sugar was full as great as the beſt acre in the ſame piece, and the expenſe of boiling was little more than a ſixth part of the other, and he ſold the Sugar for ſix ſhillings per hundred weight more than he could get for the other.

The time for planting the Canes is always in the rainy ſeaſons, and the ſooner they are planted after the rains have begun to fall, the more time they will have to get ſtrength before the dry weather ſets in; for when they have put out good roots, and are well eſtabliſhed in the ground, they will not be ſo liable to ſuffer by the drought, as thoſe which have but newly taken root.

The ſeaſon being come for planting, the ground ſhould be marked out by a line, that the rows of Canes may be ſtraight, and at equal diſtances; but firſt it will be proper to divide the piece into lands of ſixty or ſeventy feet broad, leaving intervals between each of about fifteen feet; theſe will be found of great uſe

Digitized by Google

when the Canes are cut, for roads in which the carriages may paſs to carry off the Canes to the mill; for where there is not ſuch proviſion made, the carriages are obliged to paſs over the heads of the Canes to their no ſmall prejudice: beſides, by theſe intervals, the ſun and air will have freer paſſage between the Canes, whereby they will be better ripened, and their juice will be fuller of ſalts; therefore when the Canes are ground, they will not require ſo much fuel to boil their juice. The middle of theſe intervals may be planted with Yams, Potatoes, or other eſculent plants, which may be taken off before the Canes are cut, that the paſſages may be clear for the carriages; but a path ſhould be left on the ſides of each land, for the more convenient riding or walking of the overſeer of the plantation, to view and obſerve how the labour is performed.

The common method now practiſed in planting of the Canes is, to make a trench with a hoe, which is performed by hand; into this one negro drops the number of cuttings intended for planting, at the diſtance the hills are deſigned; theſe are by other negroes placed in their proper poſition, then the earth is drawn about the hills with a hoe, all this is performed by hand; but if the right uſe of ploughs was well known in thoſe countries; the work might be much better performed, and for leſs than half the expenſe; if inſtead of making a trench with a hoe, a deep furrow were made with a plough, and the cuttings properly laid therein, the ground would be deeper ſtirred, and there would be more depth for placing the Canes.

If the ground is to be afterwards kept clean with the horſe hoe, the rows of Canes ſhould be planted five feet aſunder, that there may be room for the horſe and plough to paſs between them; and the diſtance of the hills from each other ſhould be two feet and a half, and but one Cane ſhould be permitted to remain in each hill. After the Canes are planted and have made ſome ſhoots, the ſooner the horſe plough is uſed the better will the Canes thrive, and the ground will be eaſier kept clean from weeds; for if theſe are torn up when they are young, they will preſently die; whereas when they are ſuffered to grow large before they are diſturbed, they are with great difficulty deſtroyed.

As the growth of the Canes is promoted according to the cleanneſs of the ground, ſo there cannot be too much care taken to keep the Canes perfectly clear of weeds; and the beginning of this work ſoon will render it leſs troubleſome, and it may be performed at a leſs expenſe, than when it is neglected for ſome time. When this is performed with a plough, the earth in the interval ſhould be thrown up to the rows of Canes, firſt on one ſide of the row, being careful not to diſturb the roots of the Canes, as alſo not to bury their new ſhoots; and in the ſecond operation, the earth ſhould be turned over to the other ſide of the rows, with the ſame care as before. By this turning and ſtirring of the land, it will be rendered looſer, and the earthing of the plants will greatly ſtrengthen them; ſo that from each hill there will be as many ſhoots produced as can be well nouriſhed, and the ſun and air will have free ingreſs among the rows, which will be of the greateſt ſervice to the Canes.

When the Canes are from ſeven to ten feet high, and of a proportionable ſize, the ſkin ſmooth, dry, and brittle, if they are heavy, their pith gray, or inclinable to brown, the juice ſweet and glutinous, they are eſteemed in perfection.

The time for cutting the Canes is uſually after they have grown ſix months; but there ſhould not be a fixed period for this, for in ſome ſeaſons and in different ſoils, there will be more than a month's difference in their maturity; and thoſe who have made the experiments of cutting their Canes before they were ripe, and letting others ſtand till after they were ripe, have found the Sugar made from the latter, was much finer than that of the former, though the quantity was not quite ſo great; however, it will always be beſt to let them ſtand till they are in perfection before they are cut, but not longer.

They have alſo found thoſe Canes which are cut towards the end of the dry ſeaſons, before the rains begin to fall, have produced better Sugar than thoſe which are cut in the rainy ſeaſons, when they are more replete with watery juice, and there has been much leſs expenſe of fuel to boil it, which is a material article in large plantations; therefore the better the Canes are nouriſhed in their growth, and the more ſun and air is permitted to paſs between the rows, the leſs expenſe will be incurred in boiling and preparing the Sugar.

[The manner of preparing the ſtiff ſoils in the Weſt Indian iſlands for Sugar, is to burn the traſh and weeds upon it, as ſoon as the Canes are cut down; the aſhes being a proper manure; and the beſt compoſt for ſuch land is aſhes, ſand and rotten cane-traſh. This land ſhould always be hoe-ploughed, and after continuing about a month in this ſtate, it ſhould be *holed*. The cane-holes ſhould not be very deep, ſo as to bring up the ſtiff clay. It is better to hoe-plough the bottoms of the cane-holes, juſt before throwing in the manure; and if they are not planted ſoon after, the manure ſhould be covered with a little mould, taken from the ſides of the banks. The plants muſt be laid dry, and not more than two inches below the ſurface, unleſs you are forced to plant in dry weather, which ſeldom happens.

The Cane rattoons better in ſtiff than in light ſoil. Coffee, Cocoa and Plantains thrive very well in it.

In light ſoils, ſuch as ſand, gravel and all poor dry moulds, with lime-ſtone or rock of any kind under it; the traſh and weeds ſhould be dug into the ground at the time of holing. No ploughing is neceſſary, but labour is beſt beſtowed in preparing and carrying on good rich manure, without which theſe light ſoils will never make a proper return to the planter.

The manure muſt be laid on heaps to ferment and rot, and if it is not arrived at a ſufficient ſtate of putrefaction at the time of planting, it may be diſtributed to the young plants, when they are a foot or eighteen inches above the ground. This work ſhould be done in rainy weather, that the ſalts may the ſooner penetrate to the roots of the young Canes.

In theſe ſoils you muſt plant either very early or very late. If you plant in may or june, which is termed ſpring-planting, and the weather proves favourable, the plants may be fit to cut in april or may following. But where ſituation, dry weather, a late crop, want of ſtrength in ſlaves or cattle, &c. prevent this early planting; the month of december will be the beſt time—or even early in january. In light ſoils you can hardly make your cane-holes too deep, and the buſineſs of planting may ſucceed immediately to that of holing.

Cotton, Indian Corn and moſt of the roots flouriſh beſt in theſe light ſoils.

In both ſoils, when the plants are about ſix inches high, they ſhould be weeded with the hand, and no weeds, ſhould be ſuffered at any time to cover the ground, ſo as to retard the growth of the Cane. Perhaps in a very dry ſeaſon, low weeds may be of ſervice, by keeping the ground moiſt, and preventing the ſcorching ſun from penetrating to the roots of the Canes.

At every weeding, a ſmall portion of the banks is to be pulled down with the hoe, and ſpread round the young plants; but this ſhould be done ſparingly, that part of the banks may remain, to be drawn round the rattoons.

In twelve months from the time of planting, or as ſoon as the arrows have dropped, it is proper to go through them, to ſtrip off the exuberant leaves and traſh, in order to admit the ſun and air, and ripen the Canes more expeditiouſly. This is particularly neceſſary in rich or level lands.

In all deep gray ſoils, rich black and chocolate-coloured mould, manure is not ſo neceſſary, and in theſe happy ſituations crops will be produced almoſt without rule.

It is the general practice to plant cloſer in poor than in rich land: but this is an erroneous method founded probably on a notion that two Canes muſt always be better than one; without conſidering that

Digitized by Google

one good ſtrong plant will yield more Sugar than half a dozen ſmall ones. One healthy plant is ſufficient for a hole of four feet ſquare. In rich flat land, this thin method of planting is alſo very proper; for, were this ſort of ſoil to be planted cloſe, the Canes when grown up would exclude the rays of the ſun, and want that free circulation of air, ſo neceſſary to prevent diſeaſes in the Cane, as well as for the neceſſary concoction of its juices.

All expoſed ſituations indeed, where the Canes are apt to lodge, ſhould be planted cloſe; and two, or even three plants may be put in a hole of the above dimenſions; that the Canes may the better reſiſt the violence of the wind, and ſupport one another.

The great peſts of the Sugar-cane are the Cane-ants, and the blaſt ſuppoſed to be occaſioned by minute inſects which accompany them. Rats alſo are very deſtructive to it, and Knot-graſs is the moſt pernicious weed. It is thought by ſome that rich oily manures, or a thick dreſſing of marl, is the beſt cure for the ants. But many Sugar-plantations have been totally abandoned, ſuch are the ravages of theſe inſects; and the beſt courſe to purſue in this calamity, is to adopt the culture of cotton, where the ſituation is not too wet or cold. Blaſts that come without the ants may in the beginning be ſtopped by burning the parts affected; by waſhing the young plants with ſalt-water or weak lime-water; and a good ſeaſon, that is heavy ſhowers, will ſometimes put a ſtop to it. When it returns, the Canes ſhould be planted thinner, to give them a free circulation of air: the quincunx mode of planting may in this caſe be adopted with advantage. And if the leaves affected are ſtripped off, and the diſeaſed ſtems cut down, and burnt to windward; and the roots covered with good freſh mould; this with ſalt or lime water, may prove a cure for the *greaſy fly* and *yellow fly*; as well as for thoſe deſtructive worms called the *borer* and the *grub* [p].

The planters endeavour to get all their Canes off the ground before the end of april: becauſe heavy ſhowers frequently fall the end of may, when ſome ground ſhould be holed for a ſpring plant, which ſhould be put in before the end of june. The young Canes muſt alſo be weeded in theſe two months, and the produce ſhould be carted before the roads are broke up by the heavy rains. In july, auguſt and ſeptember old dung ſhould be carried out, and new prepared: and weeding continued.

In auguſt and the two following months is the proper ſeaſon for holing ſtiff land. September and october are generally rainy months; and the proper time for throwing rotten dung on the holed land. The land ſhould be planted in november and the beginning of december [q].

It is near half a century ſince Mr. Miller recommended the uſe of the plough in the culture of the Sugar-cane. Mr. Long afterwards, in 1774, earneſtly exhorted his countrymen to profit by experiments that had been made with the plough in Jamaica. Some pieces were ploughed at an eſtate in the pariſh of Clarendon, and left to lie for ſome time before they were holed by the negroes, who found it uncommonly eaſy to work. Before ploughing it was ſpread over with manure; and the Canes planted upon it turned out near three hogſheads of fine Sugar on an acre, which was one hogſhead more than it had been uſed to yield from the common method of culture. It was found that one plough turned up as much ground in a day as a hundred negroes could with their hoes, and in a much better manner. One benefit among others from the uſe of the plough is, that it makes the bottom of the furrows even, ſo that the rain water never lodges, but either ſoaks in, or runs clear and gradually off; whereas the ground dug with hoes retains the water ſome time, which checks the growth of the Canes, makes them ſhort-jointed, and in conſequence leſs yielding; nor do they bear the dry weather ſo well. The plough is of ſignal uſe in ſtiff or heavy clay land; the turning up of which with hoes is a moſt laborious tedious taſk, and has injured multitudes of negroes; who can ſcarcely get through it, except in very favourable open weather, which does not always happen at the holeing ſeaſon. In planting in the furrow after the plough, children will ſerve as well as grown negroes. The Canes uſed for this purpoſe, may be cut ſhort, three or four eyes in each junk, and one row laid in each furrow; thus with the greateſt expedition a furrow will no ſooner be cut than planted, and the whole covered in at the next return of the plough: after the planting is finiſhed, the able negroes may cover the ridges well, raiſing them higheſt towards the middle; rake the looſe earth out of the trenches; and cut croſs drains where neceſſary; all which will be an eaſy taſk, after the ſurface has been well broke and opened. Even they who prefer holeing, will find their advantage in firſt turning it up with the plough; for the negroes will be able to finiſh the work in half the time. In this caſe the land need not be cut ſo deep as when it is intended to plant in the furrow: in either caſe, one or two ploughings at moſt will be ſufficient, unleſs the land is extremely foul. More ground can be turned up and planted in one day by this method, than can be holed and planted in the uſual way in three, and with a tenth leſs number of able negroes; for as the young boys and girls, or what is commonly called the graſs-gang, may, with the ſlighteſt inſtruction, cut and lay the junks in the furrow; and a few of the abler hands will ſerve to cut and ſupply them with the Cane plants; the remainder of the able field hands may be occupied about other neceſſary work, of which there is always ſufficient on a large plantation.

Some may object, that the plough will not leave a due ſpace between the Canes: but this is a miſtaken opinion; for a ſingle line of plants, in every furrow, will not ſhoot up too thick, the ground will be all over ſmooth and even, and the wind will have a free courſe from whatever quarter it may blow; beſides, the many trenches will contribute to an open ventilation, whereas in the ordinary method of planting with the hoe, and leaving high banks, the Canes, eſpecially when young, are deprived of a very neceſſary refreſhment. In hot dry weather they are ſcorched and blighted by the reflection of the ſun-beams, which is very great from the high mounds on each ſide of them; and in time of heavy rains they are buried in a kind of wet ditch, which cannot fail of retarding their vegetation by chilling the ſtool or root. With the plough, rightly managed, that diſagreeable operation of ſupplying Canes is, in a great meaſure, prevented; for if the ſeaſon prove wet, the Canes are ſafe from being chilled by water; and if dry, their ſtools being well covered in, are at a ſufficient depth beneath the ſurface to retain their moiſture for a long time. It has been obſerved, that in ploughed ground the plants come up much ſtronger than in hoed land; this may be accounted for, not only by the more effectual looſening of the ſoil, but by giving a free vent to all noxious water; for although Canes cannot flouriſh without a good ſupply of water, yet too much of it, lodging in puddles about the roots, is greatly prejudicial, and deſtroys many acres of Canes.

It is not eaſy to calculate the work of a plough in Sugar-grounds, on account of the great variety of ſoil: but in moderate land, neither very ſtiff nor very light, it will work twenty-four acres a week; and it is certain, that at ſix hours a day, it will perform what would require the labour of ſix hundred negroes, employed during the ſame ſpace eight hours in a day. The plough therefore both ſaves the labour of many negroes, and enables the planter to cultivate many acres more than he could otherwiſe do; beſides that the Canes ſo planted yield more Sugar, and of a ſuperior quality. Stronger inducements there cannot be for planters to break through the force of prejudice and cuſtom, and bring this method of culture into uſe, wherever their land is not ſo ſteep as to render it impracticable: and even

[p] Extracted from a pamphlet, entitled Letters to a young Planter, &c. written by an old Planter on the Iſland of Grenada. Lond. 1785. oct. See alſo, an Eſſay upon Planterſhip, by Samuel Martin, Eſq. of Antigua; reprinted in Young's Annals, vol. 18. p. 236, &c.

DESCRIPTIONS, &c.

1. Root fibrous, branched, annual. Herb bright green, many-ſtemmed, branched, hirſute, ſomewhat viſcid. Stems diffuſed, leafy, dichotomous, ſcarcely panicled. Leaves elliptic-oblong; the upper ones ovate. Peduncles generally three times as long as the calyx, erect, bent back when the flowering is over, but becoming erect as the ſeed ripens. Calyx-leaves hirſute, acuminate, four; two of them interior, narrower, with a membranous margin. Petals four, ſhorter than the calyx, obcordate, white. Stamens four, ſometimes but ſeldom five. Capſule cylindric, a little longer than the calyx, burſting at the top with eight blunt teeth. Seeds ſomewhat rugged on the outſide. The flowers expand only in bright weather. In the wild plant they are always four-cleft and four-ſtamened: in cultivated luxuriant plants they are ſometimes five-cleft and five-ſtamened[t].

Native of Scotland, on ſandy ſhores and rocks, on walls and in rubbiſhy places; flowering in may and june. Dr. Smith firſt obſerved it on walls about Edinburgh, as well as on the Calton hill and Arthur's ſeat, in 1782, and communicated it to Dr. Hope. It has ſince been found by Mr. Dickſon on Inch Keith and Inch Combe in the Frith of Forth, and alſo on the beach below Preſton Pans.

Mr. Curtis inſiſts that this plant in ſtructure and habit is a Ceraſtium; and Dr. Smith, who at firſt conſidered it as a Sagina, from the number of parts in the fructification, has ſince ſubſcribed to Mr. Curtis's opinion. Having been noticed too late for me to inſert it under Ceraſtium, I have thought it better to introduce it here, than to omit it entirely.

2. Trailing Pearl-wort has a fibrous root, according to ſome annual, according to others perennial; Mr. Curtis ſays it is generally annual, but in ſhady places often perennial. Stems numerous, in ſhady moiſt places procumbent, rooting; in dry ſituations upright, two or three inches in length, round, ſmooth, jointed, branched and proliferous. Leaves half an inch long, connate, linear, mucronate, ſmooth, deep green; root-leaves in tufts. Peduncles axillary, ſolitary, longer than the leaves, one-flowered, nodding before the flowers open. Calyx ſpreading; leaflets obtuſe. Petals very ſmall, twice or thrice ſhorter than the calyx, entire, white, ſpreading; often imperfect[u]. Capſule

[t] Smith.
[u] Curtis and Smith.

ſurrounded

Digitized by Google

ſurrounded with the permanent calyx, ovate, thin, one-celled, four-valved, opening beyond the middle. Receptacle columnar, free, hiſpid, a little longer than half the capſule. Seeds more than fifty, nearly kidney-ſhaped, ſmooth, ferruginous [x].

Villars ſays that he has often ſeen this plant without any petals, with a five-leaved calyx, ten ſtamens, and five piſtils, thus approaching to Spergula. The calyx and other parts of the flower appear in this caſe to increaſe at the expenſe of the corolla; the latter however is often wanting without an augmentation of the other parts.

Mr. Curtis remarks, that few plants aſſume a greater variety of appearance than this, but that in all ſituations the ſingular appearance of the ſeed-veſſels, placed on the calyx, like a cup on a ſaucer, will eaſily diſtinguiſh it.

Native of moſt parts of Europe, Siberia and Japan, in barren paſtures, on walls, &c. Being fond of a ſandy and gravelly ſoil, it is a troubleſome little weed in garden walks and paved courts, where it flowers and ſeeds during the whole ſummer [y].

3. Annual Pearl-wort has a root certainly and conſtantly annual, ſmall and fibrous. Stems ſeveral, nearly upright, or if they ſpread never taking root, from one to three inches or more in height, round, filiform, jointed, clothed with ſhort ſcattered hairs. Leaves oppoſite, linear-ſubulate, ſhort, mucronate, frequently hairy, and always fringed at the baſe. Peduncles ſlender, at firſt nodding but afterwards upright, often but not always hairy. Petals white, frequently emarginate, very minute, and often altogether wanting. Capſule one-celled: valves larger than the leaves of the calyx. Seeds generally marked with a black line on their outer edge, but this is not abſolutely invariable [z].

Linneus was not well acquainted with the differences between this ſpecies and the preceding, with which he certainly confounded Spergula ſubulata [a].

Mr. Ray conſidered this as diſtinct from the *procumbens*; and informs us, that it differs from it not only in the colour of its ſtalks and leaves, which are of a browner hue, but that it has an annual root, and that it does not put forth roots at the joints, as the *procumbens* does.

Linneus at firſt conſidered this as a variety of that, but afterwards, convinced by Arduini, he adopted it in his ſecond Mantiſſa as a ſpecies. Mr. Hudſon continued it as a variety.

The diſtinction of an annual and perennial root, though it cannot perhaps be admitted in all caſes as a ſpecific character, muſt be allowed to have conſiderable weight. The *apetala* is as regular an annual as the *Draba verna*, while the *procumbens* continues green through the winter. The preceding is always procumbent; and when it grows, as it commonly does, in moiſt ſituations, it mats and ſpreads on the ground. The ſtalks of the *apetala*, when the plant is young, ſpread on the ground; but as it advances to maturity they riſe up, and if ſeveral grow together, become quite erect. Where the plants grow ſingly, and in a dry ſituation, they neither acquire the ſame height, nor the ſame degree of uprightneſs. Sometimes it is found on moiſt ſhady walls, but taller and more branched than common; but whether the plants be ſmall or large, their ſtalks and leaves are hairy; whereas in the *procumbens* they are perfectly ſmooth: the hairs are viſible to the naked eye, and when magnified, have no little globules at their extremities, as in thoſe of *Spergula ſaginoides*, which comes very near in its appearance to Pearl-wort. The *apetala* is a ſmaller plant than the *procumbens*, and much finer in its ſtalks: its leaves are alſo ſhorter by almoſt one half, and leſs ſucculent.

From its latin trivial name, one ſhould be led to ſuppoſe, that it is perfectly apetalous; accordingly both Linneus and Arduini deſcribe it as ſuch: it is however generally found with petals, but ſo minute, as almoſt to require a magnifier to render them viſible.

Mr. Ray does not appear to have an idea of its being a common plant, for he mentions the particular ſpots where it was to be found: but it is ſcarcely leſs frequent than the preceding, in more dry, barren and open places; on walls, in gravel walks, where it is a troubleſome weed, and on barren heaths; flowering in may and june. There is perhaps ſcarcely any plant that is quicker in ripening its ſeeds [b].

Beſides England, it is native of France, Italy and Germany.

4. Upright Pearl-wort has an annual, ſimple, fibrous root. The whole herb is ſmooth and glaucous. Stems two or three inches high, upright, ſtraight, round, purpliſh, jointed, very few, but ſometimes more numerous and divaricated. Leaves oppoſite, linear-lanceolate, acute; the lower ones ſeſſile, rigid, grooved: thoſe on the ſtem connate, often bent back, broader and more pointed. Peduncles ſolitary, very long, frequently purpliſh, one or two on a ſtalk. Calyx-leaves lanceolate, acute, with a membranous edge. Petals white, about as long as, or a little ſhorter than the calyx, undivided. Germ ovate. Stigmas almoſt ſeſſile, villoſe. Capſule cylindric, undivided, opening with eight or ten teeth, one-celled; containing many rugged kidney-ſhaped ſeeds, of an orange-brown colour [c].

This is a little plant of conſiderable neatneſs and elegance in its ſtructure, much ſtronger than either of the two preceding; growing frequently on dry gravelly paſtures and heaths among graſs, flowering in april and may [d].

The calyx never opens far, ſo that the corolla is not ſuffered fully to expand. If the ſeaſon proves dry, the ſtalk is generally ſimple; but if the ground be moiſt, it throws out many ſtalks, which firſt ſpread on the earth, and afterwards become upright [e].

The fruit, ſays Dr. Smith, as Mr. Curtis has admirably obſerved, is altogether that of Ceraſtium, but its entire petals, and the number of parts in the flower, by no means agree with that genus; nor does the habit correſpond either with Ceraſtium or the other Saginas. It may perhaps form a diſtinct genus.

Mr. Curtis was at a loſs, whether to conſider this little plant as a new genus, or to arrange it with *Sagina*: for though it agrees with *Sagina* in having a calyx and corolla each of four leaves, together with four ſtamens and as many piſtils, yet in its ſeed-veſſels it greatly reſembles a *Ceraſtium*; while the whole plant, in its habit and glaucous appearance, approaches nearly to *Stellaria holoſtea*. As there are few genera however, where the ſpecies do not vary conſiderably in the parts of fructification, he thinks it moſt eligible to continue it a *Sagina*; eſpecially as it retains thoſe characters, which obviouſly diſtinguiſh it from any of the decandrous plants.

To this determination I heartily ſubſcribe, notwithſtanding Ehrhart has made it a new genus by the name of *Moenchia*; and, as Dr. Smith thinks, perhaps not unjuſtly.

5. Stem filiform, a finger's length. Leaves oppoſite, awl-ſhaped, remote, very ſmall. One flower terminating, and ſome oppoſite, each on its proper peduncle. Calyx four-parted, upright. Petals four, oblong. Stamens four, the length of the calyx. Germ conical, the length of the calyx. No ſtyle. Stigma blunt. Capſule pyramidal, beaked, one-celled. Seeds numerous. Perhaps it may be of a genus peculiar to itſelf.

Native of Virginia, where Clayton found it among moſs on the brink of ſprings [f].

Here is another doubt concerning the genus of a ſpecies of *Sagina*. The firſt ſpecies is removed to *Ceraſtium*. The fourth and fifth are thought worthy of making each a diſtinct genus. Thus we may have almoſt as many genera as ſpecies; ſcarcely any two ſpecies agreeing in their habit, and in all the parts of their fructification.

The ſeveral ſpecies may eaſily be increaſed by their ſeed, which they ſhed abundantly.

SAGINA. See *Stellaria*.

SAGITTA. See *Sagittaria*.

SAGITTÆ SIMILIS. See *Pontederia*.]

DESCRIPTIONS, &c.

1. Root perennial, conſiſting of a tuber fixed deeply in the mud. Stem and petioles triangular, very ſpongy, by which they are ſupported in the water in conſequence of the air generated within them: they diſcharge a white milky juice, an uncommon circumſtance in aquatic plants[g]. The petioles are in length proportioned to the depth of the water in which the plant grows, and are ſometimes almoſt a yard long. [Leaves all from the root: the firſt, which are always under water, long and linear: the ſucceeding leaves, which riſe above the water, are arrow-ſhaped, very entire, ſmooth, with parallel ribs, and a net-work of veins. Flowers three in each whorl, each having a ſmall oval-lanceolate bracte at the baſe of the pedicel, embracing the ſtem. One or two of the lower whorls have female, the reſt male flowers. The pedicels of the latter are an inch long; of the former about half an inch, and ſtronger. Calyx of one leaf with three diviſions[h]. Corolla white, with a purpliſh tinge at the claws of the petals, ſoon falling off[i]; but there is a ſucceſſion of the flowers through the months of july and auguſt[k]. Stamens three, according to Gærtner, who conſiders what Linneus calls the ſeeds as utricular capſules, before maturity lenticular-compreſſed, but afterwards membranaceous-bracted, ſubſemilunar, terminated by a very ſhort recurved ſtyle, one-celled, not opening, of a pale ſtraw-colour. Common receptacle globular, naked, covered with ſmall dots: proper receptacle, a ſhort filiform cord ſtretched from the baſe of the capſule within the cell, ſupporting the ſeed; which is ovate-oblong, having a longitudinal ſtreak on each ſide from the navel, thus appearing as if it were doubled; it is covered with very minute dots, and is rufeſcent.

Dr. Stokes[h] remarks, that the flowers which are called male, have from one to five piſtils, and that there are none with ſtamens only. Dr. Smith ſays, that he has obſerved three or four piſtils in ſome of the male flowers; but whether they ever ripen is uncertain. They ſhould therefore rather be called imperfect hermaphrodites.

The young plant with linear leaves is well figured in Flora danica: not ſo, in Petiver, *t.* 43. *f.* 9. Roemer's figure is copied from Engliſh Botany. The two figures of the great and ſmall Arrow-head in Ger. emac. and Parkinſon are from Dodonæus. The leaſt Arrow-head of Gerarde is omitted by both theſe, but copied by Petiver.

Native of Europe, Siberia, China, Cochinchina, Japan and Virginia in pools, ditches and ſlow ſtreams; of which it is one of the moſt beautiful ornaments throughout England.

The bulb or tuber, which fixes itſelf in the ſolid earth below the mud, conſtitutes a conſiderable part of the food among the Chineſe, and upon that account they cultivate it[l]. The roots are larger there; in the Eaſt Indies, where they are alſo eaten; and in America. In Europe they are neglected, being probably acrid and cauſtic.

Arrow-head varies much in ſize, and has leaves of different forms; hence ſeveral varieties, and pretended ſpecies of old authors[m]. Loeſelius's variety (δ of Linneus) is imaginary; for Arrow-head has always both ſagittate and linear leaves: Mr. Miller however (n. 2.) is tempted to conſider it as a different ſpecies.] With reſpect to Plukenet's leaſt Arrow-head, he is willing to impute the ſmallneſs of the leaves, and the ſhortneſs of the petioles and peduncles to ſituation; it being covered only at high water, which may ſtint its growth, and give it the peculiar appearance which it puts on.

[2. This differs from the preceding in having the anterior part of the leaves twice as wide as in that.—Native of Aſia[n].

3. Leaves acuminate both ways, quite entire, ſhining, coriaceous, on round and very long petioles. Spikes of flowers a foot or two longer than the leaves. Of theſe there are four partial ones; the middle longer than the three outer. Peduncles one-flowered, three together. Flowers twice as large as thoſe of the common ſort; with a reddiſh calyx, white petals, and yellow anthers. Fruit depreſſed [o].

The ſtem grows very luxuriant in general, and riſes frequently to the height of two or three feet above the foliage. The branches of the lower whorls ſeldom exceed three in number, and are commonly ſubdivided in the ſame manner themſelves; but thoſe of the higher orders conſiſt chiefly of five long ſimple flower-ſtalks, and thoſe about the top of three only. The flowers that grow about the extremities of the ſtem and branches are generally male, and ſtand on longer peduncles than the female flowers, which commonly occupy the lower part of the main and lateral flower-ſpikes. Both the ſtalk and branches are ſmooth and roundiſh [p].

Native of Jamaica and Cuba in ſtagnant waters.

4. This has the ſtature of the common ſort. Leaves ſheathing at the baſe, convex outwards, ſharp at the edge, gradually attenuated into a compreſſed cuſp without any widened leaf. Flowers reſembling thoſe of the firſt ſort. Stamens many. Fruit a very cloſe globe of acute ſeeds.—Native of Surinam, in water [q].

5. Native of China.

SPECIES.

1. Salacia chinenſis.

Lin. ſyſt. 820. *Reich.* 4. 44. *mant.* 293.

Stem ſhrubby, leaves quite entire alternate, flowers ſeveral axillary.

2. Salacia cochinchinenſis.

Lour. cochinch. 526. *ed. Willd.* 642.

Stem ſhrubby, leaves ſubſerrate oppoſite, flowers heaped axillary.

DESCRIPTIONS, &c.

1. Branches angular, even, divaricating very much, thickiſh at the baſe. Leaves petioled, remote, oval, like thoſe of the Plum, ſharpiſh, even. Flowers many from each germ, on one-flowered peduncles ſhorter than the petiole.—Native of China [r].

2. Stem almoſt upright, ſix feet high, with many twiſted branches. Leaves ovate, ſubacuminate, ſmooth, petioled. Flowers of a reddiſh yellow colour, ſmall. Berry roundiſh, unequal, reddiſh, middle-ſized, eatable. Calyx inferior, coloured. Petals concave, ſpreading, longer than the calyx. Filaments none. Anthers roundiſh, two-lobed, diſtant. Germ round-flatted. Style none. *Stigma* a very ſmall point.—Native of Cochinchina, among buſhes [s].]

SALICARIA. See *Lythrum.*

SALICORNIA. (*From* Sal, *ſalt, and* Cornu, *a horn.*)

Lin. gen. n. 10. *Reich. n* 10. *Schreb. n.* 14. *Tournef. t.* 485. *Juſſ.* 86. *Gærtn. t.* 127.

Claſſ. 1. 1. Monandria Monogynia.

Nat. order of *Holoraceæ. Atriplices,* Juſſ.

GENERIC CHARACTER.

CAL. four-cornered, truncate, ventricoſe, permanent.

COR. none.

STAM. *Filaments* one, (or two) ſimple, longer than the calyx. *Anther* one, oblong, twin, erect.

PIST. *Germ* ovate-oblong. *Style* ſimple, under the ſtamen. *Stigma* bifid.

PER. none. *Calyx* ventricoſe, inflated.

SEED ſingle.

OBS. *I ſaw long ſince one ſtamen in a cultivated plant of the annual ſpecies: others afterwards obſerved two filaments. In another ſpecies from Virginia, of which I had a living ſpecimen lately under view, the calyx was an ovate ſcale, concave like a ſnail's-ſhell, and upright: it had certainly two ſtamens, and a ſuperior piſtil.* Syſt. veg. p. 51. *Forſter and Moebring both reckon two ſtamens in Salicornia herbacea. Baſter only one.*

ESSENTIAL CHARACTER.

Cal. ventricoſe, entire. *Pet.* none. *Stam.* one or two. *Seed* one covered by the calyx.

SPECIES.

Leaves cordate embracing.

9. Salicornia caſpica. *Caſpian jointed Glaſſwort.*

Lin. ſpec. 5. *Reich.* 1. 9. *Willd.* 1. 26. *Lepech. it.* 1. 254. *Pallas it.* 1. *app. n.* 90. *t.* D. *f.* 2.

Kali arboreſcens, tamariſci facie. *Buxb. cent.* 1. *t.* 11. *f.* 1.

Joints cylindric, ſpikes filiform.

DESCRIPTIONS, *&c.*

1. Root fibrous, ſmall, annual or biennial. Stem for the moſt part upright, ſubdivided at the baſe, branched at top: branches oppoſite, ſimple, upright, very ſucculent, leafleſs, jointed; joints flatted, widening at the end, emarginate. Spikes oppoſite, with one at the end larger than the reſt, peduncled, round, gradually attenuated towards the top, ſharpiſh, jointed. Flowers oppoſite, near together, moſtly three on each ſide in the clefts of the joint.

The variety β has a more branching ſtem, with longer and thicker ſpikes:—γ a diffuſed ſtem, with very long ſpikes:—δ a very branching ſtem, with ſmall purpliſh ſpikes:—ε a very branching ſtem, firmer than in the others, with ſhort green ſpikes[t].

The young plants are herbaceous, the older ones ſuffruteſcent, or ſomewhat woody at bottom; in this ſtate they have been ſometimes miſtaken for the next ſpecies[u]: that however is diſtinct, and a native of England as well as this; which may be known from it by its herbaceous ſtem being much ſhorter and more branched, but eſpecially by the marks given in the ſpecific characters.

[t] Smith. [u] Withering.

This plant is common on the coaſt of Europe, Aſia, Africa and America, where the ſhore is flat and oozy: and flowers with us in auguſt and ſeptember. The three firſt varieties were found by Mr. Stoneſtreet, in a little ſalt-marſh on the eaſt ſide of Pool in Dorſetſhire: the laſt was alſo gathered by the ſame gentleman, but in what place is not mentioned.

The whole plant has a ſaltiſh taſte, and is greedily devoured by cattle. Steeped in ſalted vinegar, the tender ſhoots are made into a pickle, which is taken for the true Sampire, or *Crithmum maritimum*; which ſee. Hence its name of *Marſh Sampire.*

2. Native of Siberia, by the Jaik in drier marſhes.

3. Root woody, perennial. Stem ſuffruticoſe, aſcending, very much branched; branches and branchlets oppoſite and leſs fleſhy. All the internodes almoſt cylindric. Spikes commonly ſeſſile, altogether cylindric, blunt, many-flowered, with very ſhort joints[x].

Native of Europe and Africa, in the ſame ſituation. In England Sir Hans Sloane found it near the Iſle of Shepey; Dillenius in greater plenty in the Iſle of Grain; Mr. Yalden on the ſhore all the way from Weymouth turnpike to Rhodipole.

Theſe plants are burnt, and from the aſhes a foſſile alkali is obtained, which is in great requeſt for making ſoap and glaſs. Hence their names of *Glaſſwort* and *Saltwort.* It is chiefly made on the coaſt of the Mediterranean, where it is called Soda[y]. The Tuniſians collect theſe and other ſea plants, and when they are almoſt dry, burn them in a pit made for the purpoſe. The French merchants purchaſe the ſalt, and ſend it to Marſeilles for making ſoap[z].

Linneus ſays, that they have no plant more adapted to the making of Soda; but though the quantity of foſſil alkali which it yields is very conſiderable, a great portion of it is mixed with the muriatic acid, and therefore it contains much common ſalt[a]. Many other plants are uſed for this purpoſe, but of theſe ſee under the article SALSOLA.

4. Native of the Caſpian ſea.

5. Branches oppoſite, undivided, terminated by a long jointed ſpike. It is diſtinct from the firſt ſpecies, which is alſo found in Virginia. S. virginica, obſerved by Scholler in ſalts in Germany, is only a variety of that[b].

6. This is a ſhrub, with alternate divided branches. Leaves fleſhy, blunt, covering the branchlets, opening on one ſide alternately.

Native of Arabia[c], and Barbary: obſerved by Rauwolff about Tripoli. This is burnt for Kelp or Soda.—Cultivated in 1758, by Mr. Miller[d].

7. This is a ſhrub, with alternate almoſt ſimple branches. Leaves fleſhy.—Native of Siberia, where it was found by Gmelin[e].

8. Stem decumbent, fruteſcent at the baſe, a hand or little more in height, very much branched: branches from all the axils of the leaves, alternate, ſpreading very much, an inch and half long, two together very near each other. Leaves ſmall, alternate, bluntiſh, beneath convex, above flattiſh; on the younger branches imbricate. On the ſhores of a lake near Bardo in the kingdom of Tunis[f].

9. In muddy places by the Caſpian ſea, and in Media[g].

Forſter has a ſpecies (prodr. n. 489.) found in New Zealand, which he has named *Salicornia auſtralis.*

SALISBURIA. (*So named, by Dr. Smith, in honour of Richard Anthony Saliſbury, Eſq. F.R.S. and F.L.S.*)

Lin. tranſ. 3. 330.

SPECIES.

1. Saliſburia adiantifolia.
Smith in Lin. tranſ. 3. 330.
Ginkgo biloba. *Lin. mant.* 313. *Dict. noſtr.*

DESCRIPTION, *&c.*

This large and not inelegant tree is cultivated in China and Japan. It has been long (upwards of forty years) admired for its handſome fan-ſhaped leaves, cloven about half way from their ſummit; but they can by no means be termed two-lobed, that denomination requiring that the ſegments ſhould be rounded. Theſe leaves are alſo irregularly notched like thoſe of the *Zamiæ*, thickened at the margin, ſmooth, ſtriated on each ſide with numerous parallel nerves.

The fruit is a pale-brown drupe, of a globular form; the fleſh or pulp hard and thick; the ſhell is thin, bony, oval, triangular, ſmooth, ſharp at the top and one-celled; the ſeed or kernel ſolitary, filling the ſhell, having two coats brown and membranous, one adhering to the ſhell, the other to the ſeed; albumen greeniſh-white, of the ſame form with the ſeed, like that of the almond; embryo yellow, inſerted into the baſe of the albumen, ſtraight, dicotyledonous. The fruit is not produced till the tree arrives at a conſiderable age.

This genus ſhould be placed in the Linnean ſyſtem between *Quercus* and *Juglans*. In that of Monſ. de Juſſieu it belongs to the fifth order of his fifteenth claſs (Coniferæ) after *Taxus*; though it is not very nearly allied to any genus whatever.

Dr. Smith has preferred *adiantifolia* for the ſpecific name, becauſe *biloba* is not correct, and *adiantifolia* has not only been uſed long ago by Kæmpfer and Thunberg, but is peculiarly appoſite in this caſe, Mr. Saliſbury preferring ſuch comparative ſpecific names to all others.

The generic name of *Ginkgo*, being equally uncouth and barbarous, was retained by Linnæus in an appendix, only till the flowers ſhould be diſcovered, and the plant referred to its proper place in the ſyſtem [h].

For the reſt ſee GINKGO.]

SALIX. (*A ſaliendo*; *from the quickneſs of its growth.*—*Gr.* ΙΤΕΑ, *παρα το ιεναι*; *on the ſame account.*)
Lin. gen. n. 1098. *Reich. n.* 1201. *Schreb. n.* 1493. *Tournef. t.* 364. *Juſſ.* 408. *Gærtn. t.* 90. *Hoffm.* 17.
Claſſ. 22. 2. Dioecia Diandria.
Nat. order of *Amentaceæ*.

GENERIC CHARACTER.

* *Male.*

CAL. *Ament* oblong, imbricate every way, (conſtructed of an involucre from the bud,) conſiſting of *Scales* one-flowered, oblong, flat, ſpreading.
COR. *Petals* none.
Nectary a gland cylindric, very ſmall, truncate, melliferous, in the centre of the flower.
STAM. *Filaments* two, ſtraight, filiform, longer than the calyx. *Anthers* twin, four-celled.

* *Female.*

CAL. *Ament* and *Scales* as in the male.
COR. none.
PIST. *Germ* ovate, attenuated into a *Style* ſcarcely diſtinct, a little longer than the ſcales of the calyx. *Stigmas* two, bifid, erect.
PER. *Capſule* ovate-ſubulate, one-celled, two-valved: *valves* revolute.
SEEDS numerous, ovate, very ſmall, crowned with a ſimple hirſute *pappus* or down.
OBS. *In ſome ſpecies, the male flowers have three or five ſtamens of unequal length; three have them monadelphous, another as in the claſs Syngeneſia.*
S. hermaphroditica *is the only ſpecies known to us which has hermaphrodite two-ſtamened flowers.*
S. purpurea *and* Helix *have only one ſtamen to the flowers.*

[h] Smith in Linn. tranſ.

ESSENTIAL CHARACTER.

Cal. Ament compoſed of ſcales. *Cor.* none.
MALE. *Nectary* a melliferous gland.
FEM. *Style* biſid. *Capſ.* one-celled, two-valved. *Seeds* downy.

SPECIES.

S. folio lato ſplendente fragilis. *Raii cant.* 143. *hiſt.* 1420.
S. fol. longo latoque ſplendente fragilis. *Raii ſyn.* 448. 8.
Leaves ſerrate ſmooth ovate-lanceolate, petioles tooth-glandular.

14. Salix babylonica. *Weeping Willow.*
Lin. ſpec. 1443. *Reich.* 4. 226. *hort. cliff.* 454. *Gron. orient.* 307. *Du Roi harbecc.* 2. 397. *Medic. in obſ. ſoc. æcon. Lutr.* 1774. *p.* 287. *Gouan illuſtr* 77. *Gmel. it.* 3. 309. *t.* 34. *f.* 2. *Lour. cochinch.* 609. *ed. Willd.* 747. *Pallas roſſ.* 1. 78.
S. orientalis, flagellis deorſum pulchre pendentibus. *Tournef. cor.* 41. *Duham. arb.* 20.
S. arabica foliis atriplicis. *Baub. pin.* 475. *Raii hiſt.* 1424.
S. humilis arab. fol. atripl. *Park. theat.* 1433. 7.
Garb arabum. *Rauw. itin.* 183. *Dalech. app.* 30.
Leaves ſerrate ſmooth linear-lanceolate, branches pendulous.

15. Salix purpurea. *Bitter purple Willow.*
Lin. ſpec. 1444. *ſyſt.* 879. *Reich.* 4. 226. *fl. ſuec. n.* 884. *Hudſ. angl.* 427. *Smith in Linn. tranſ.* 6. 113. *Teeſd. in Linn. tranſ.* 5. 71. *Pollich pal. n.* 919.
S. monandra. *Hoffm. ſal.* 1. 18. *t.* 1. *f.* 1, 2. *t.* 5. *f.* 1. *t.* 23. *f.* 1. *Wither. arr. ed.* 3. 45. *Curt. lond.* 6. *t.* 71. *Sibth. oxon. n.* 48.
S. humilior, foliis anguſtis ſubcæruleis, ex adverſo binis. *Raii cant.* 144. *n.* 5. *hiſt.* 1421. *n.* 9. *ſyn.* 448.
One-ſtamened, leaves obovate-lanceolate ſerrate ſmooth, ſtigmas very ſhort ovate ſubſeſſile.

16. Salix Helix. *Roſe Willow.*
Lin. ſpec. 1444. *Reich.* 4. 226. *Hudſ. angl.* 427. *Smith in Linn. tranſ.* 6. 114. *Teeſd. in Linn. tranſ.* 5. 71. *Hall. helv. n.* 1640. *Deſfont. atlant.* 362. *Dalech. hiſt.* 277. *f.* 2.

Salicis racemi ſ. nucamenta, roſæ & capitula ſquamata. *Baub. hiſt.* 1. 2. 213.
One-ſtamened, leaves lanceolate acuminate ſerrulate ſmooth, ſtyle elongated filiform, ſtigmas linear.

17. Salix fiſſa. *Baſket Oſier.*
Hoffm. ſal. 1. 61. *t.* 13. 14. *Smith in Linn. tranſ.* 6. 115.
Monadelphous, leaves lanceolate acute ſomewhat toothletted ſmooth glaucous underneath.

18. Salix rubra. *Green Oſier.*
Hudſ. angl. 428. *Wither. arr. ed.* 3. 49. *Smith in Linn. tranſ.* 6. 116.
S. virescens. *Villars dauph.* 3. 785. *t.* 51. *f.* 30.
S. minime fragilis, foliis longiſſimis utrinque viridibus non ſerratis. *Raii ſyn.* 449. *n.* 14.
S. nerii folio utrinque virente. *Vaill. par.* 175. *ed. Mart.* 2. 227.
S. rubra minime fragilis folio longo anguſto. *Baub. hiſt.* 1. 215. *Raii hiſt.* 1421. *n.* 8.
Monadelphous, leaves linear-lanceolate elongated acute toothletted ſmooth, of the ſame colour on both ſides.

19. Salix Croweana. *Broad-leaved monadelphous Willow.*
Smith in Linn. tranſ. 6. 117.
Monadelphous, leaves elliptic ſubſerrate very ſmooth, glaucous underneath.

20. Salix myrſinites. *Whortle-leaved Willow.*
Lin. ſpec. 1445. *Reich.* 4. 227. *fl. lapp. n.* 353. *t.* 8. *f.* f. & *t.* 7. *f.* 6. *ſuec. n.* 885. *Hoffm. ſal.* 1. 71. *t.* 17. 18. *Gunn. norv. n.* 595. *Gouan illuſtr.* 76. *Leers, herborn. n.* 753. *Hall. helv. n.* 1645.—*ſec. Hoffm.* 1647. *Villars dauph.* 3. 769. *t.* 50. *f.* 12.
S. retuſa. *Dickſ. in Linn. tranſ.* 2. 288. *Wither. arr. ed.* 3. 48.
S. alpina pumila myrſinites. *Ponted. comp.* 149.
S. alp. foliis anguſtioribus ſplendentibus ſerratis. *Scheuch. alp.* 340.
Leaves ſerrate ſmooth ovate veined.

21. Salix arbuſcula.
Lin. ſpec. 1445. *ſyſt.* 879. *Reich.* 4. 227. *fl. lapp. n.* 360. *f.* m. *ſuec. n.* 886. *Gmel. ſib.* 1. 166. *Pallas roſſ.* 1. 80. 83. *Gouan. illuſtr.* 76. *Jacqu. auſtr.* 5. *t.* 408. *Hall. helv. n.* 1647. *Retz. obſ.* 6. 34. *Villars dauph.* 3. 771.
Leaves ſubſerrate ſmooth ſubdiaphanous glaucous underneath, ſtem ſuffruticoſe.

22. Salix herbacea. *Herbaceous Willow.*
Lin. ſpec. 1445. *ſyſt.* 879. *Reich.* 4. 228. *fl. lapp. n.* 355. *t.* 7. *f.* 3. ♂. *f.* 4. ♀. & *t.* 8. *f.* 4. *ſuec. n.* 887. *Hoffm. ſal.* 1. 74. *t.* 20. *f.* 1, 2, 3, 4. *Hudſ. angl.* 427. *Wither. arr. ed.* 3. 48. *Lightf. ſcot.* 600. *Gunn. norv.* 51. *n.* 3. *Fl. dan. t.* 117. *Jacqu. vind.* 296. *Gouan illuſtr.* 77. *Pallas it.* 3. 33. *roſſ.* 1. 85. *Hall. helv. n.* 1649. *Villars dauph.* 3. 773. *Allion. pedem. n.* 1967.
S. ſaxatilis minima. *Baub. pin.* 474. *prodr.* 159.
S. alpina min. lucida repens Alni rotundo folio. *Bocc. muſ.* 2. 19.—item, S. alp. Alni rot. folio repens. *Ej. t.* 1. *f.* ult. *Raii hiſt. ſuppl.* 12. *ſyn.* 448. 7.
Leaves ſerrate ſmooth orbicular.

23. Salix retuſa. *Blunt-leaved Willow.*
Lin. ſpec. 1445. *Reich.* 4. 228. *Hall. helv. n.* 1648. *Gouan. illuſtr.* 76. *Villars dauph.* 3. 772. *Pallas roſſ.* 1. 85.
S. alpina anguſtifolia repens non incana. *Baub. pin.* 474. *prodr.* 159.
S. alp. ſerpylli folio lucido. *Bocc. muſ.* 2. 18. *t.* 1.
S. puſilla humilis. *Camer. epit.* 104.
Leaves ſubſerrate ſmooth obovate very blunt.

24. Salix decipiens.
Hoffm. ſal. 2. 9. *t.* 31.
Leaves ſerrate ſmooth lanceolate petioled, the lower ones ſmaller obovate reflex.

25. Salix arbutifolia. *Arbutus-leaved Willow.*
Pallas roſſ. 1. 79.
S. pumila folio ovali baſi ſerrato. *Gmel. ſib.* 1. 160. *t.* 35. *f.* 2?
Leaves obovate acute ſerrate ſmooth.

26. Salix divaricata. *Straddling-branched Willow.*
Pallas roſſ. 1. 80.
Leaves ovate-lanceolate wave-ſerrate ſmooth, branches divaricate.

S. folio utrinque glauco, viminibus albidioribus. *Raii cant.* 142. 2.
Leaves lanceolate acuminate ſerrate pubeſcent on both ſides, the loweſt ſerratures glandular.

[53. Salix tetraſperma. *Four-ſeeded Willow.*
Roxb. corom. 66. *t.* 97.
Leaves broad-lanceolate acuminate ſerrulate, ſmooth above whitiſh below.

DESCRIPTIONS, *&c.*

Linneus remarked, almoſt half a century ago, that the ſpecies of the genus Salix are not to be extricated without extreme difficulty: that the ſoil and ſituation, marſhy, ſandy, mountainous, hot and cold, produced a conſiderable change in them, inſomuch that botaniſts frequently heſitated whether they ſhould pronounce many differences to conſtitute ſpecies or varieties only: add to this, that the deſcriptions of the old authors are in general imperfect and barbarous.

He adviſes therefore the hiſtory of Willows to be taken up afreſh, rejecting the old names, and deſcribing the ſeveral ſpecies accurately by means of ſkilful perſons who have an opportunity of viewing them in their natural places of growth; and who ſhould attend to the following circumſtances. 1. Whether the buds are one-valved, or many-valved. 2. The ſituation and folding of the leaves within the bud. 3. Whether the aments or catkins come from the ſame or a diſtinct bud from the leaves, above or below them. 4. Whether the leaves are ſerrate or quite entire about the edge, naked or pubeſcent on the ſurfaces. 5. What is the number of ſtamens. 6. Whether they are trees, ſhrubs, or creeping.

To theſe hints of Linneus Dr. Smith has added, that Willows require to be examined at three periods of their growth: firſt when in flower, at which time the leaves in general ſcarcely appear; next when the capſules are fully formed and nearly ripe, and the leaves juſt expanded with their ſtipules; laſtly when the leaves have attained their full ſize, and all remains of the fructification have diſappeared. In this laſt ſtate the true form, and pubeſcence or ſmoothneſs of the leaves is to be known; in the ſecond the nature of the ſtipules, which frequently are very deciduous, and the figure and ſurface of the capſules; whereas in the firſt ſtate the very diſcriminative and curious parts of the flower, the ſtamens, nectaries, and above all, the proportion and ſtructure of the germ, ſtyle and ſtigmas, are only to be learnt. Dr. Smith recommends theſe laſt-mentioned parts as affording much better characters for making natural ſubdiviſions of the genus, than the margin or pubeſcence of the leaves, if we could at all times command them: but the dioecous nature of theſe plants militates againſt a general arrangement of them according to parts, which it is an even chance whether we meet with or not, and which are ſo very tranſient[b].

Ray ſo far back as the year 1660 diſtinguiſhed and deſcribed very well ten ſpecies, which he obſerved himſelf about Cambridge; ſeparating the Willows with a more compact leaf, from the Sallows and Oſiers which have a leaf of a looſer texture; and correcting the error of old authors in ſuppoſing that the roſe-like excreſcences at the ends of the twigs in ſome Willows formed a diſtinct ſpecies.

Dillenius's edition of Ray's ſynopſis, in 1724, has twenty-two ſpecies of Engliſh Willows, ſome of which are only varieties. Mr. Hudſon, in 1778, has only ſixteen, but he has ſeveral varieties, which are real ſpecies. Mr. Lightfoot, in 1777, has the ſame number, but not the ſame ſpecies. He has deſcribed moſt of them at length; and Dr. Smith having compared his ſpecimens with thoſe in the Linnean herbarium, all difficulties reſpecting his ſpecies will be removed.

Haller, in 1768, has twenty-one ſpecies, but it is not eaſy to aſcertain them all with any degree of certainty. Scopoli, in 1772, has only twelve ſorts, which he has named and deſcribed with little reference to other authors. With his uſual modeſty he confeſſes himſelf to be unfortunate in extricating the ſpecies; and after all his attempts, owns that he has found only ſtill greater difficulties and miſtakes, the more he has conſulted writings even of the firſt reputation. Villars, in 1789, enumerates thirty ſpecies, natives of Dauphiné: he has taken much pains in deſcribing and aſcertaining them.

George Francis Hoffmann publiſhed the firſt faſciculus of his elaborate hiſtory of Willows in 1785, and completed his firſt volume in 1787; it contains twelve ſpecies, completely deſcribed, and beautifully figured. The firſt faſciculus of his ſecond volume, containing three ſpecies, came out in 1791. This is all I have ſeen of a work, ſo full, ſo accurate, I might almoſt ſay ſo perfect, as far as it goes, in the opinion of the judicious preſident of the Linnean Society. If Dr. Hoffmann goes on to deſcribe and figure the other ſpecies in the ſame manner, little or no doubt can remain concerning them. In the mean time we may expect moſt of the difficulties reſpecting the Briti-

[b] Linn. tranſ. 6. 111.

Digitized by Google

S A L

tiſh ſpecies to be cleared up by Dr. Smith, in his Flora Britannica, ſo far at leaſt as can be expected without figures. The opportunity he has of ſtudying Linneus's original ſpecimens, and of comparing them with Mr. Lightfoot's: the aſſiſtance he has received from his accurate and indefatigable friend Mr. Crowe, who has for many years collected Willows, both indigenous and exotic, from all quarters, carefully noticing their peculiar uſes and properties, diſtinguiſhing the truly wild from the naturalized, and watching them with a moſt diſcriminating eye through all their ſtages of growth in his garden[i]; together with his own accurate reſearch, and happy judgement, give Dr. Smith an advantage which has not perhaps fallen to the lot of any other man. The editor of this Dictionary has to lament that this article goes to preſs before he can profit by all the obſervations and corrections which may be expected in the Flora Britannica; at the ſame time that he is happy to acknowledge the aſſiſtance he has received from Dr. Smith's learned remarks, printed but not yet publiſhed in the Tranſactions of the Linnean Society; as well as that candid information by letter which he is ever ready to afford.

We may obſerve in general of this genus, that it contains trees or ſhrubs, ſome few ſpecies ſuffruticoſe or even ſubherbaceous; that the flowers and fruits are in ſeparate axillary or terminating aments or catkins, which, when young, are covered with a ſingle ſcale like a veil[k]. All the ſpecies except four are natives of Europe; and thirty-four or thirty-five are indigenous of Britain.

Willows, ſays Scopoli, ſupport the banks of rivers, ſupply bands or withs, feed a great variety of inſects, rejoice the bees, yield abundance of fire-wood, dry marſhy ſoil, afford nouriſhment to cattle with their leaves, and yield a ſuccedaneum to Jeſuit's bark.

The uſes of the Willow, including the Sallow and Oſier, are thus minutely detailed by the venerable Evelyn.—All kinds of baſket-work; for which even our rude forefathers were in eſtimation at Rome—

> "Barbara depictis veni *Baſcauda* Britannis;
> "Sed me jam mavult dicere Roma ſuam."
>
> *Martial.*

For pill-boxes, cart-ſaddle trees, gun-ſtocks and half-pikes, harrows, ſhoemaker's laſts, heels, clogs for pattens, forks, rakes eſpecially the teeth, pearches, rafters for hovels, ladders, poles for hops vines kidney-beans, &c. hurdles, ſieves, lattices; for the turner in making great town-tops, platters, little caſks and veſſels, eſpecially to preſerve verjuice in: pales, dorſers, fruit-baſkets, cans, hives, trenchers, trays, boards for whetting table-knives, coals, particularly for painter's ſcriblets; bavin and excellent ſweet firing without ſmoke. The wood will even endure a good while for poles, &c. if it be peeled and ſteeped in water for ſome months.

The ancient Britons made boats of wicker covered with ſkins (coracles) with which they paſſed rivers and arms of the ſea; ſo light as to be carried by a ſingle man. Modern Britons wield bats of Willow, in the game of Cricket.

1. This agrees with S. pentandra in its ſmooth leaves, bluntly ſerrate with glands, convolute, commonly ſix from each bud, yellowiſh; and in having villoſe aments of the ſame ſize and habit: but it differs from it in having the branches of a pale ruſſet-colour, not purpliſh; the upper ſurface of the leaves with ſcored not raiſed veins; protuberant glands at the baſe of the petioles; in flowering earlier, and producing a greater abundance of galls than the next ſpecies. Native of Sweden about Upſala[l], but not common. It is generally and almoſt wholly covered with a red coccus, ſo ſmall as almoſt to eſcape the ſight. In the year 1754 all the flowers excluded their ſtamens, and in their place appeared ſeſſile rudiments of anthers, on each ſide of the nectary, like three glands[m].

The real *hermaphroditica* of the Linnean herbarium is cloſely allied to *S. pentandra* except in the fructification; and has no right to a place among Britiſh plants. Hudſon introduces it with a mark of doubt; and S. latifolia folio ſplendente of Ray, ſeems by Dillenius's remark, to be a variety of the Sallow. What is found in the gardens under the name of *hermaphroditica*, is merely a broad-leaved variety of *S. pentandra*, which is dioecous and has five ſtamens: whereas the true *hermaphroditica* has but two ſtamens, and thoſe in the ſame flower with the piſtil. It does not ſeem to be known out of Sweden[n].

2. This is naturally a tree thirty feet or more in height, but being one of the beſt Oſiers for the uſe of Baſket-makers is generally cut and kept low. The bark of the ſtem and branches peels off ſpontaneouſly, almoſt like that of the plane-tree. The branches are upright, long, ſlender, pliable and tough, though ſomewhat brittle at their inſertion; their bark is browniſh and ſmooth. Leaves about three or four inches long, tapering away towards the baſe, and their breadth on each ſide the nerve is as nearly equal as poſſible; they terminate in a point; their margin is thickly ſerrate, the ſerratures incurved and rounded, a little glandular; both ſides ſmooth, the under rather glaucous. Stipules ovate, oblique, crenate, veiny, ſmooth, but often wanting. Catkins at the ends of ſmall leafy young branches, erect, ſlender, yelloviſh, with blunt downy ſcales. Stamens generally three to each ſcale, very rarely (in the ſame catkin) only two. Germ ovate, pointed, warty. Stigmas ſhort, ſpreading, notched. Capſule very ſmooth, green[o].

Mr. Curtis remarks that the leaves are more ſtrongly ſerrate than moſt others; that the branches in autumn are uſually furniſhed with ſtipules, but not always; and that towards the top they are angular or grooved, in a greater degree than any other Willow he has examined. It is not uſual for Willows to flower both in ſpring and autumn, but he has frequently found this ſpecies to do ſo.

Native of many parts of Europe; as Britain, Germany, Switzerland, France, Flanders, Carniola, Piedmont, &c. common alſo in Siberia.

This ſpecies may be admitted into ornamental plantations, the male catkins being very numerous, of a bright yellow colour, and of an agreeable ſcent. The male tree ſhould on this account be preferred for ornament; and alſo becauſe the females quickly ſhed their catkins and make a litter[p]. Mr. Wood remarks that the male tree is very frequent, and that he had ſeen the female only once. He obſerved it about Leeds; and Mr. Crowe at Lakenham near Norwich. The bark in doſes of one or two drams will cure an ague[q]. It flowers in april or may. Villars ſays that the female flowers much later, namely in june; that the wood of theſe is more brittle, the leaves narrower, ſmooth on both ſides, and harder: but perhaps it may be a different ſpecies.

Some authors confound this with the *amygdalina*; and give Ray's ſynonym of *S. folio auriculato ſplendente flexilis*, which belongs to that ſpecies.

Ray has marked their difference. The leaves of this, ſays he, are longer and narrower than in the *amygdalina*, produced into very long ſlender points, of a dark green ſhining as if poliſhed, approaching in form to thoſe of the Almond or Peach, elegantly toothed about the edges, having an appendix at the baſe on each ſide more conſpicuous than in other ſorts of Willow, beſides the earlets (ſtipules) at the baſe of the petioles on each ſide faſtened to the twigs, which are ſmaller in this than in the *amygdalina*. The bark of the ſtem and older branches is aſh-coloured, chopped, and parts readily from the wood; this is alſo the caſe in the *amygdalina*, but not ſo manifeſtly. The colour of the twigs is yellow.

3. The ſweet or bay-leaved Willow is ſufficiently well known by its broad odoriferous leaves, the ſerratures of which exude a copious yellow reſin, and its numerous ſtamens, commonly about five to each flower[r].

It frequently grows to a tree ten or twelve feet high, with a trunk as large as a man's thigh: the twigs are

[i] Linn. tranſ. 112. [k] Juſſieu. [l] Linn. ſpec. [m] Linn. ſuec. [n] Smith in Linn. tranſ. 6. 112. [o] Idem, 118. [p] Curtis. [q] Withering. [r] Smith in Linn. tranſ.

Digitized by Google

of a reddiſh colour tinged with yellow: the leaves are ſtiff, ſhining ſmooth on both ſides, finely ſerrate with cloſe numerous cartilaginous teeth; when full grown they are about three inches long, and an inch and half wide: their footſtalks are ſhort, broad, and ſprinkled with glands: each ſcale in the male catkin has uſually five ſtamens, but often ſix, and ſometimes ſeven. Theſe catkins are very ſweet-ſcented[s].

According to Mr. Gough, there are eleven leaves on the barren, and ſix or eight on the fertile ſhoots, the two lower comparatively ſmall and obovate. The nectaries are often wanting in the flowers at the extremity of the catkin, in room of which there are three additional perfect ſtamens.

Dr. Stokes remarks, that the nectaries are three, yelloviſh brown, two near the ſpike-ſtalk, and the third next the ſcale:—and Mr. Stackhouſe, that the catkins terminate the new ſhoot of the year, and do not appear until may.

This ſpecies, ſays Villars, is eaſily known by its broad leaves like thoſe of Bay, green on both ſides, a little clammy, having regular ſharp teeth, by its five ſtamens, and its yellow long thin catkins; and yet ſometimes *S. fragilis* approaches ſo near to it as ſcarcely to be diſtinguiſhed, except by the clammineſs of the leaves.

Ray deſcribes the young twigs as very dark-coloured; the leaves wider than in any other Willow, ſmooth, dark green and ſhining above, paler beneath, from two to three inches long, an inch and half or more in breadth, with ſmall notches on the edge, on ſhort petioles, alternate, ſweet-ſcented: they are ſhorter and wider in proportion than thoſe of *S. fragilis*.

Native of ſeveral parts of Europe, as Britain, Switzerland, Dauphiné, Piedmont; alſo of Siberia.—In Weſtmoreland and Yorkſhire, frequent, as about Kendal and Bradford. About Kilnſay and Carr end Wenſledale, where it is the moſt common ſpecies. Near Stafford, and in Mr. Boulton's plantations, Soho, Birmingham. Near Bungay in Suffolk, Coombe wood, and near Wimbledon in Surry. Scotland.

Much uſed in Yorkſhire for making the larger ſort of baſkets; the branches are cut to make ſpringles; the leaves afford a yellow die; the wood crackles greatly in the fire[t]. The down of the ſeeds, mixed with a third part of cotton, has been proved to be a very good ſubſtitute for cotton itſelf, and has been uſed for ſtuffing cuſhions, wicks for candles, &c. Goldfinches and ſome other birds line their neſts with the down of this and other ſpecies of Willow[u].

Variety β of Flora Suecica ſeems to be a diſtinct ſpecies, not yet found in England[x].

4. This appears to be a ſhrub, with ſmooth ſlender ſpreading branches. Leaves alternate, petioled, exactly lanceolate, rather acute, with broad and unequal crenatures principally about the middle, and between theſe in a manner ſinuate; the margin is a little more thickened than ordinary; the baſe and extremity of each leaf are entire, deſtitute of glands; all the leaves are either perfectly ſmooth in every part or a little ſprinkled with minute inconſpicuous hairs; dark green above, glaucous and reticulated with veins beneath. Footſtalks ſlender, ſmooth. Stipules creſcent-ſhaped, moſtly ſerrate, various in ſize[y].

Native of Lapland, and the northern parts of Sweden: about Herborn, according to Leers: and on the highlands of Scotland, where it was found at Finlarig, Breadalbane, with ſeveral others, by the Rev. Mr. Stuart, junior, of Killin, in Breadalbane, and communicated to Mr. Lightfoot, in whoſe herbarium this was diſcovered by Dr. Smith, and by him added to the Britiſh Flora.

5. The trunk ſcarcely riſes to the height or form of a tree. The branches are upright, round, rather brittle, ſmooth. Leaves two or three inches long, acute, a little rounded at the baſe, crenate in almoſt every part, but more ſlightly in the female plant; dark green and very ſmooth above; glaucous, veiny, rarely a little hairy beneath. Foot-ſtalks very broad at their baſe. Stipules, if preſent, rather large, obliquely heart-ſhaped, ſerrate, ſmooth. Catkins from an inch to an inch and half long, thickiſh, with obovate brown hairy ſcales. The two ſtamens are diſtinct, and more or leſs hairy about their baſe. Style ſhort, ſmooth. Stigmas thick, ovate, united at their baſe, permanent, undivided. Capſules on foot-ſtalks, long and tapering, clothed with long ſilky down, as are the general and partial ſtalks.

The leaves in the female plant are ſhorter and leſs crenate, as well as more tapering towards the baſe. Such differences between the two ſexes of Willows are rare, but I can hardly conceive theſe to be different ſpecies, as they agree in every part beſides.

No writer except Linneus appears to have known this Willow. In his Flora Lapponica he diſtinguiſhed it, but in his Species Plantarum he made it a variety of the *phylicifolia*, from which it differs in the much greater ſize of all its parts, as well as in the totally different form of its ſerratures, a part ſo peculiarly characteriſtic of the *phylicifolia*. It is named *nigricans* from the dark colour of its branches, as well as its black hue when dried, which laſt indeed is not abſolutely peculiar to it.

Native of Lapland; and found at Wrongay fen, Norfolk, and in oſier grounds in other places not uncommon, by Mr. Crowe.

6. Very nearly related to the laſt, but certainly a diſtinct ſpecies. It eſſentially differs in the male catkins, which are but half the ſize of thoſe laſt deſcribed, and their ſtamens are ſhorter, perfectly ſmooth, not hairy at their baſe. The leaves alſo are of a brighter green, their margin inclined to be revolute, and rather toothed than crenate. The germ alſo is ſhorter, blunter, and leſs tapering.

Found in oſier-holts and marſhy grounds by Mr. Dickſon, flowering in april and may.

7. This ſpecies has moſt affinity with the two preceding, but has longer and more ſlender twigs. The leaves are four or five inches long, about an inch broad, pointed, ſomewhat revolute, generally a little unequal at the baſe, bright green, ſmooth and ſhining above, glaucous and ſometimes a little hairy beneath. In drying they turn a purpliſh black. The footſtalks are peculiarly long, linear, and ſlender, ſilky on the upper ſide. Stipules ſmall, creſcent-ſhaped, toothed, ſmooth. Female catkins ſcarcely an inch long, with black, hairy, obovate, often notched ſcales. Germs on long footſtalks, ſmall, ovate, ſilky. Stigmas perfectly ſeſſile, ovate, obtuſe, divided into two lobes.

It was ſent to Mr. Crowe by Mr. Dickſon along with the laſt as of Britiſh growth. It flowers in april[z].

8. This is a middle-ſized tree, with round flexuoſe upright cinereous ſmooth divided branches. Leaves alternate, acuminate, ſmooth on both ſides, except while young, when they are villoſe; they are a finger's length and the petioles are very ſhort. Flowers from the ſame bud with the leaves.—Native of Japan, and flowering there in march[a].

Loureiro ſuſpects that this is not ſpecifically diſtinct from the *babylonica* or weeping Willow, although the branches are flexuoſe only, not pendulous.

9. The Yellow Willow is a middle-ſized tree, much branched at the top: branches upright. Bark gray, chopped, cinnamon-coloured within, bitter and aſtringent. The female trees, when left to themſelves, have pendant branches, but when lopped, are ſtiff and ſtraight. Male catkins at firſt upright, then turned down; cylindrical, ſlender, ſerpentine, two inches long or more; on fruitſtalks half an inch long. Nectaries two. Stamens two. Female catkins from two to three inches in length, on fruitſtalks from an inch to an inch and half long. Leaves alternate, upright, ſlightly ſerrate, with a yelloviſh midrib; they are about three inches long and one inch broad, but always broader in the female tree. Stipules none. Glands very few. The male tree is generally ſmaller and leſs common than the female.

Native of the more temperate parts of Europe.

[s] Lightfoot. [t] Withering. [u] Haller and Lightf. [x] Smith in Linn. tranſ. [y] Idem. [z] Smith in Linn. tranſ. [a] Thunberg.

Digitized by Google

Common in England, but doubtful whether it be indigenous. Haller regarded it as a variety of *S. alba*; and had a notion that if it were left wholly to itſelf it might degenerate into that ſpecies.

The ſhoots are uſed by baſket-makers. The wood is white and very tough. The cotton will make ordinary paper, and may ſerve ſome of the purpoſes of genuine cotton. The bark may be uſed in dyeing, and medicinally in agues[b]. It is common all over Ruſſia, and is uſed for Palms at Eaſter in the Greek churches[c].

10. This never riſes into a tree. The bark is deciduous, as in *S. triandra*, which added to the triandrous flowers perhaps led to the ſuſpicion that there exiſted no ſpecific difference between the two ſpecies: the leaves however will ſufficiently ſerve to diſcriminate them. Thoſe of *S. amygdalina* are ſhorter, ſcarcely two inches long, of a broadiſh ovate figure rounded at the baſe, by no means linear; they are moreover oblique, the width of the two ſides being unequal. The ſtipules are remarkably large, varying from a roundiſh to an half-heartſhaped form, crenate, deciduous. Female flowers and capſules much as in *S. triandra*[d].

There is much confuſion in the ſynonyms of this ſpecies. Ray calls it the round-eared ſhining Willow, and has marked it very well by its large ſtipules, three ſtamens, and other characters.—Villars ſuſpects it to be *n.* 1638. of Haller. It is certain that the illuſtrious Swiſs aſſigns the ſame ſynonym of Ray to his *n.* 1638, that we do to this.

Native of ſeveral parts of Europe, in oſier-holts and marſhes. Obſerved by Mr. Crowe, on Badley-mere by Dereham, Norfolk.

11. This is diſtinguiſhed by its ſeſſile ovate ſmooth leaves, ſharply and very finely but ſcarce apparently ſerrate; and its ſubcordate ſtipules.—It becomes a tree, but never tall. Branches round, very ſtraight, cinereous. Leaves hard, with very minute and ſcarcely viſible ſerratures, cinereous beneath, but ſmooth on both ſides, rigid, appendicled with two ovate entire leaflets[e].

Native of Lapland, Weſtrobothnia, Germany, Switzerland, Ruſſia and Siberia.—Introduced about 1780, by Meſſrs. Kennedy and Lee.

12. This tree grows to a conſiderable height. Leaves oblong, very large, hoary beneath, crenate about the edges[f].—Native of Egypt, and of Barbary near la Calle.

Retzius refers *S. nitida* of Gmelin to this ſpecies, although the leaves of that are ſaid to be entire and ſomewhat hairy. A ſweet water is diſtilled from the catkins, whence the Perſian name of *Biedmuſk* or *Baedmuſch*, ſignifying Water-muſk.

13. This grows to be one of the largeſt trees of the genus. The branches break off eaſily at the ſhoot of the preceding year. Leaves large, four inches long, an inch and half broad, diſtinctly and deeply ſerrate, ſmooth and ſhining on the upper ſide, glaucous underneath. Stipules ſcarcely any, but inſtead of them the footſtalks are dotted with prominent glands. The catkins have two or three fugacious leaves at the baſe of the peduncle[g].

Villars remarks, that though the branches are brittle on the tree, yet they are pliant when it is young or kept down for oſiers; and that the male flowers have ſometimes three ſtamens.

Native of the greater part of Europe eſpecially the northern parts; alſo of the temperate and ſouthern parts of Ruſſia to the limits of Caucaſus.

This tree is of quick growth and ſoon forms a ſhade in wet places; the males are fitteſt for this purpoſe. Bees are fond of the male flowers[h].

The bark of the branches manifeſts a conſiderable degree of bitterneſs to the taſte, and is alſo aſtringent; hence it has been thought a good ſubſtitute for the Peruvian bark, and has been recommended in caſes requiring tonic or aſtringent medicines. Not only the bark of this ſpecies, but that of ſeveral others, poſſeſſes the ſame qualities, particularly the *alba* and *pentandra*. The bark of the latter is perhaps the beſt; at leaſt its ſenſible qualities give it a decided preference[i].

14. The Weeping Willow grows to a conſiderable ſize, I have one in my view whilſt I am writing which is four feet and a half in circumference at three feet above the ground, and is at leaſt thirty feet in height; the age is thirty-four years. This tree is remarkable and generally eſteemed for its long ſlender pendulous branches, which give it a peculiar character, and render it a beautiful object on the margin of ſtreams or pools. Leaves minutely and ſharply ſerrate, ſmooth on both ſides, glaucous underneath, with the midrib whitiſh; on ſhort petioles. Stipules, when preſent, roundiſh or ſemilunar and very ſmall; but more frequently wanting, and then in their ſtead a glandular dot on each ſide. Catkins axillary, ſmall, oblong: in the male the filaments longer than the ſcale, with two ovate erect glands faſtened to the baſe: the female, on two leaved peduncles ſcarcely longer than half an inch[k].

Native of the Levant. Every where in the Cherſoneſus Taurica, but probably not indigenous there. Spontaneous on the coaſt of Perſia[l]. Frequent in China. Cultivated, but not commonly in Cochinchina[m]. According to an account of rare plants, with figures, publiſhed by the London gardeners, it was cultivated here in 1730[n].

The St. James's Chronicle (*n.* 6817. aug. 25 to 27. 1801.) has the following paragraph, but on what authority I know not. "The famous and admired Weeping Willow, planted by Pope, which has lately been felled to the ground, came from Spain, incloſing a preſent to the late lady Suffolk. Mr. Pope was in company when the covering was taken off; he obſerved that the pieces of ſtick appeared as if they had ſome vegetation, and added, perhaps they may produce ſomething we have not in England. Under this idea he planted it in his garden, and it produced the Willow tree that has given birth to ſo many others."

15. This is a buſhy ſhrub three or four feet high, with long ſlender tough purple ſhining branches. Leaves ſome oppoſite others alternate, nearly linear, but broadeſt upwards, ſerrate chiefly towards the ſummit, very ſmooth, glaucous beneath, deſtitute of ſtipules. The male catkins are very ſlender, ſcarcely an inch long, nearly ſeſſile, conſiſting of many thick-ſet flowers, the uppermoſt of which expand firſt. Scales black at the tip, hairy. Nectary a ſolitary gland oppoſite to each ſcale. Stamen one ſolitary ſimple, never dividing, bearing an orange-coloured double or four-lobed anther. Female catkins exactly like the male in ſize and form. Germ ſeſſile, ſmall, of an ovate or rather elliptic form, ſilky. Style very ſhort or ſcarcely any. Stigmas ſmall, ſeſſile, ſomewhat ovate, undivided, marked with a longitudinal furrow on the upper ſide. Capſule ovate, ſmall, ſilky[o].

The preſent ſpecies is particularly diſtinguiſhed by the length, as well as delicate ſlenderneſs of its twigs, and its ſubglaucous ſpurge-like leaves, but above all, by their extreme bitterneſs when chewed. The leaves vary greatly both in ſize and breadth, and ſtill more in their notchings. The ſtalks alſo vary much in colour, being ſometimes almoſt yellow. The leaves on the ſummits of the twigs are ſometimes found towards the end of auguſt of a brilliant red colour. The tops of the branches are found expanded into little ſquamous heads (as in the *alba* and others), ſomewhat reſembling roſes; this is the work of an inſect. The anthers, before they open, are of a bright orange colour[p].

Native of many parts of Europe. It grows ſparingly in the neighbourhood of London, commonly in hedges, ſometimes in oſier-grounds, where it is introduced accidentally: in ſome parts of the north of

England

England, there is no Willow more common. Mr. Teesdale marks it about Beverley, and observes that female plants seem to be rare. I have frequently gathered it in the place marked by Ray in his Cambridge catalogue. He calls it the yellow dwarf Willow. It is the earliest in bloom of any of the species, flowering in mild seasons by the end of february, usually before the *caprea*.

The extreme bitterness of the leaves and twigs, renders it very valuable for many purposes. When used as a band or withe, it is never eaten by vermin; nor, when formed into a hedge, is it browsed on by cattle; even insects prey on it much less readily than on the other species. In some parts of Yorkshire, its twigs are used for making the finest sorts of basket work. By some observations I have made, says Mr. Curtis, I should think it might be advantageously cultivated for such purposes. Planting cuttings of all the common Willows one year by way of experiment, he found that this species gave the longest one year's shoot, exceeding even that of *S. viminalis*, or *Osier*[q].

Linneus celebrates it for its toughness: *rami tenacissimi omnium*; and says that they are red, *sanguineo-coralini*; or as he expresses it in the *Flora suecica*—*verno tempore saturate purpurei*. In bands for thatching, he says it lasts above a century in Scania; he recommends it as the best sort for basket work, and most excellent for hedges.

The leaves become of a blueish black colour in drying. The bark, from its extreme bitterness, may probably prove the most efficacious of any in agues[r].

16. This rises to the height of nine or ten feet, and is a small slender tree. Even in the form of its leaves it differs from the *purpurea*, being more truly lanceolate and taper-pointed, by no means obovate. The female catkins are somewhat longer, and twice as thick as in the last, and stand on longer stalks. The germ is sessile, ovate and silky; but the style is considerably lengthened out, quite smooth and naked. The stigmas also, instead of being short and ovate, are linear and considerably elongated. The leaves are less glaucous beneath, and not so bitter as those of *S. purpurea*. From the size which Haller ascribes to his *Salix*, *n.* 1640, Dr. Smith ventures to presume he intended this plant, and not the *purpurea*, he therefore borrows from Haller the character of one stamen, having never seen the male of this species himself.

Haller and Ehrhart seem to have led Professor Hoffmann into the error of confounding this with the preceding. Mr. Curtis, and some others of our more recent writers have followed Hoffmann, perhaps without ever having seen the true S. Helix. Mr. Crowe first pointed out to Dr. Smith the different heights of the two plants and sizes of the catkins; and on a critical examination of the female flowers our acute President found farther marks of distinction. It occurs in osier-holts and marshes: flowering in march and april[s].

The rose-like excrescencies are more common at the ends of the branches in this species; whence its name of Rose-Willow[t].

Mr. Teesdale observed the following distinctions between the *Helix* and *purpurea* in their native places of growth. In the month of march, previous to their flowering, the bark of the young shoot of *S. purpurea* is of a dark purple, and the scales of the buds are a fine red, almost scarlet, generally tipped with black, and before they drop off they turn wholly black: at the same time, the bark of the young shoots of *S. Helix* is of a yellowish brown, and the scales of the buds are always of a pale brown or chestnut colour[u].

Desfontaines describes the branches as slender, rod-like, often purplish; the leaves smooth, narrow-lanceolate, serrulate but sometimes quite entire, glaucous beneath, on short petioles; the lower alternate, the upper ones opposite. Both male and female catkins slender. One stamen. The down long.

Haller informs us, that this Willow is planted about Aigle, to keep up gravelly banks and the shores of rivers.—Native of several parts of Europe, in osier-holts and marshes: flowering in march and april.

17. This is a shrub four or five feet high, with upright flexible and very tough branches, of a yellowish ash-colour, often purplish. Leaves alternate, on footstalks, two or three inches long, minutely toothed or somewhat serrate, principally towards the top; smooth on both sides except when very young; dark green above, glaucous beneath. Stipules none. Catkins on short stalks, cylindrical, blunt, first red, then yellow, flowering first at the top. The two stamens are united from the base about half way to the top. Anthers two-lobed, yellow. Germ ovate, acute, hairy. Style short. Stigmas oblong, blunt, undivided[x].

Native of some parts of Europe on the sandy banks of rivers, flowering in april, and ripening the seed in may[y].

With us it is cultivated in the fens, and preferred to all other Willows or Osiers for basket work.—Observed in several osier-grounds near Lynn in Norfolk, by Mr. Crowe; at Prickwillow near Ely, by the Rev. Mr. Hemsted; and at Hincham in Norfolk, by the Rev. Joseph Forby[z].

Hoffmann suspects that it may be the *Salix Elaagnos* of Scopoli, n. 1210.

18. The branches of this shrub are very long, slender, tough, smooth, gray or purplish. Leaves about four inches long when full grown, slightly toothed or serrate by no means entire, of a bright green on both sides, smooth in general but sometimes sprinkled with a few slender hairs beneath. Stipules, if present, linear-lanceolate, a little toothed; but generally wanting. The female catkins differ but little from the preceding, except in having thicker almost ovate stigmas. Dr. Smith presumes from analogy that the male catkins have monadelphous stamens; but he has not seen them.

This species appears to be little known, though among the most valuable as an Osier. The habit of the plant, figure and length of its leaves, agree with the common Osier; (*S. viminalis*) but their bright green colour on both sides, and want of all pubescence, except when very young, render them easily distinguishable from that species, whilst their great length, linear form, and narrowness, and their colour being not at all glaucous, prevent their being confounded with *S. fissa*. Hudson's name *rubra* is less opposite than might have been wished: *virens* or *concolor* would better have expressed the peculiar character of the species[a].

Native of England and France in osier-holts, but less common; it flowers in april and may. In the osier-holts between Maidenhead and Windsor. Found afterwards by the river near Salisbury, by Mr. James Sherard in company with Mr. Rand[b]. In an osier-holt near Ely, by the Rev. Dr. Goodenough; at Prickwillow near Ely, by the Rev. Mr. Hemsted; near Bedford, by the Rev. Mr. Abbot[c].

19. This scarcely rises to the height of a tree. The branches are short and spreading, rather brittle, clothed with a shining yellowish or purplish bark. Leaves on footstalks, elliptical or inclining to obovate, somewhat pointed, scarcely an inch and half long, slightly serrate or rather crenate, smooth on both sides, bright green and shining above, glaucous and veiny beneath. Catkins nearly sessile, of a short somewhat ovate form. Scales obovate, black, very hairy. Stamens pale lemon-coloured, longish, their filaments united from the base to a greater or less distance, sometimes almost to the top. Anthers reddish.

This species seems to have escaped the notice of every botanist hitherto. Dr. Smith has therefore given it the name of its discoverer. It is most certainly very distinct from all others, and easily known by its united stamens, and short broad leaves. It is destitute of the valuable properties of an Osier, having short and rather brittle, not long and flexible twigs. It has therefore to all appearance never been cultivated, but is truly wild in Norfolk; where Mr. Crowe found it, among other places at Cranberry fen in

the pariſh of Eaſt Winch. It flowers in april and may [d].

20. This is a ſhrub ſome feet in height, with a ſmooth bark of a dark brown or blackiſh colour, and diffuſed but upright branches. Leaves during the flowering ovate or obovate, ſmooth on both ſides, thin and nearly tranſparent, finely and acutely toothed, on ſhort ſtiff leaf-ſtalks: afterwards an inch broad and more than an inch long, both ſides of the ſame colour, ſerrate all round, pointed at the end. Leaflet often an inch and half long, furniſhed with ſtipules of a ſquariſh irregular figure, and ſerrate. Male catkins crowded, oblong or ovate-oblong, from an inch to an inch and half in length, on ſhort fruit-ſtalks: ſtamens two: nectary one. Female catkins ſhorter than the other when in flower, ovate-oblong. Capſule on a pedicel, very ſmooth [e].

Linneus deſcribes it as a ſhrub from a foot to two feet in height: very much branched; branches purpliſh and tough. Leaves alternate but in cluſters, ſtreaked with veins, having glandular ſerratures about the edge, when they firſt come out a little hairy, but afterwards ſmooth on both ſides; on little or no petioles. Stipules none. Catkins villoſe, cinereous. Anthers brown. Peduncle from the ſame bud with the leaves. Germ cinereous-villoſe, but becoming ſmooth as it ripens [f].

Native of the mountains of Scotland, Lapland, Norway, Germany, Switzerland, Dauphiné and Italy. Mr. Dickſon, who took it for *S. retuſa*, found it on Ben Lawers in 1789 [g].—Hoffmann's figure in *t.* 19. and *t.* 24. *f.* 2. are Dr. Smith's *prunifolia*, which is the *myrſinites* of Lightfoot, but not of Linneus [h].

21. Scarcely a foot high, growing in form of a little tree. Stems ſlender, filiform, branched, reddiſh. Leaves lanceolate, acuminate at both ends, on very thin looſe petioles, ſerrate on both ſides with eight or five notches ſo ſmall as to be ſcarcely viſible [i]. Stipules none. In the Flora Suecica three varieties are ſet down, agreeing in place, appearance and ſtature, all having leaves ſo thin as to be almoſt tranſparent, and glaucous beneath; the capſules in all ſilky-villoſe [k]. But the third of theſe varieties is a diſtinct ſpecies, according to Afzelius, who has named it *foliolosa*. The leaves are quite entire and ovate-oblong [l].

In cultivation it grows to the height of a man, and has thicker leaves [m].

Pallas has it twice, in p. 80 and 83 of his Flora Roſſica.

According to Retzius, the *arbuſcula* of Jacquin does not ſeem to be the ſame with that of Lapland, where it grows in ſandy moiſtiſh ground. I can ſcarcely think it to be Haller's *n.* 1647. But it ſeems to be the arbuſcula of Villars.

22. This, though named *herbacea*, is not properly an herbaceous plant, but truly a ſhrub or tree, and the ſmalleſt yet known; being only from one to three inches in height. The bark is aſh-coloured or brown. Branches irregular, knotty, ſcarcely an inch in length, ſtriking root, having ſeldom more than three leaves. Leaves roundiſh or ovate, very minutely ſerrate, the largeſt near an inch in diameter, blunt or ſlightly notched at the end, ſmooth, petioled. In the male they are nearly orbicular or wider than they are long, a little notched at the top: in the female rather cordate and not emarginate. Lightfoot compares their ſize with that of a ſilver penny. Stipules none. Peduncle from the ſame bud with the leaves. Catkins terminating, upright. Males ſome lines in length, yellow, on peduncles as long as themſelves: ſtamens two: nectaries two. Females ſhorter than the males, red, ſmooth, on peduncles of the ſame length [n].

Native of many parts of Europe, on high mountains. In the northern counties of England, Scotland and Wales: flowering in june and july.

Mr. Lightfoot has gathered it nine inches high, with ſome of the leaves as big as a ſhilling. It puts on this appearance when it grows out of the crevices of rocks, and is very old. Linneus (in Flora lapp.) has figured the male plant of the largeſt ſize that it ever appears in Lapland.

23. This contends for the prize of littleneſs with the preceding. The leaves have parallel veins [o].

A foot high. Leaves very ſmooth and ſhining, elliptic, the younger and lower ones perfectly round, on the longer branches lanceolate, ſerrate. Catkins conſtantly ſmooth, with large ovate blunt ſmooth ſcales, and two long ſtamens; they have few flowers, and on the higheſt alps occur with one flower only [p].

Stem quite proſtrate, not unfrequently with all the branches on one ſide. The flowering buds are mixed with the leafing or branching buds. Catkins very long, with widiſh concave ſcales, often emarginate. Primary leaves ſuborbiculate, the reſt oblong, ſometimes acute, often blunt and emarginate; either quite entire or ſerrulate about the middle without any ſtipules. This is quite diſtinct from the *myrtilloides*, although Haller has united them [q].

Native of Dauphiné, Switzerland, Auſtria, Italy.—Introduced in 1763, by the Earl of Coventry [r].

24. This is a tree or ſhrub with abundance of diffuſed ſcattered branches, brittle eſpecially at the joints: bark ſhining green or yellow ſomewhat cinereous. Male catkins two to five, ſcattered, alternate, firſt upright then horizontal, flexuoſe, ſubhirſute, ovate-oblong becoming cylindrical, from an inch to an inch and half in length, on a round peduncle, half an inch long, ſmooth or very finely villoſe. Stamens two, ſeldom three. Nectaries two. Female catkins alſo ſcattered, more numerous than the males, alternate, erect, cylindrical, from two to three inches long, ſubhirſute, on a peduncle half an inch in length, ſubtomentoſe and round. Germ ovate-attenuated, greeniſh, peduncled; ſtyle ſcarcely diſtinct, depreſſed in the middle; ſtigmas four, blunt, yellow. Nectary ſimple ſhort truncate blunt, on the peduncle of the germ. Capſule ovate-oblong, acuminate, peduncled, when ripe yellowiſh green or browniſh. Down long, ſilky.

Several ſpecies beſides this, ſnap off eaſily at the joints, like the *fragilis*, and are probably confounded with that, from this obvious circumſtance.

Hoffmann has named this *decipiens*, becauſe it reſembles another ſpecies ſo much, that an incurious obſerver might eaſily be *deceived* in taking them for the ſame.

Native of Europe, on the banks of rivers: flowering in may. The capſules ripen in june [s].

25. Branches upright, teſtaceous-brown; annual ſhoots ſhort, alternate, very leafy. Leaves without ſtipules, on very ſhort petioles, attenuated towards the petiole, becoming gradually almoſt entire. About the lake Baikal, and in all the eaſt of Siberia to Kamtchatka. It is a low ſhrub.

26. Trunk the thickneſs of the human finger or thumb, very much and forkedly branched from the very bottom: branches very ſhort, rigid, preſſed cloſe to the ground, browniſh yellow. Leaves at the ends of the branches frequent, in ſome lanceolate, almoſt entire; in others ovate-lanceolate, largely toothed with blunt and ſomewhat waved ſerratures. Very ſmooth and without ſtipules. Female aments among the leaves, ſubſeſſile, leafleſs, ſcarcely an inch long, cluſtered, having a thick cloſe down.

It approaches very near to the *phylicifolia* of Linneus, in its leaves.

On Sochondo one of the loftieſt mountains of Dauria, ſpreading itſelf on the granite rocks.

27. Twigs ſcarcely a foot long, bay-coloured, and branched a little. Leaves very ſmooth, produced towards the petiole, rounded at the top, bluntly ſerrate or crenulate, more or leſs glaucous beneath.

In the ſubalpine marſhes of Siberia from Obo to Baikal.

28. This is a little ſhrub, ſpreading over rocks that are covered with moſs, about the ſize of *Arbutus alpina*, with a trunk at moſt the ſize of the little finger,

with a yellowiſh and ſomewhat jointed bark, more rugged on the trunk; with ſhortiſh branches crowded and twiſted together. (In Kamtchatka, the twigs are a foot or a foot and half long, and more ſlenderly ſtretched out.) Leaves on the outmoſt branches very much cluſtered, ſmall, netted with thickiſh veins, rigid; toothlets diſtant, ſpreading a little, acuminate, unequal. Male catkins among the old leaves, from the terminating buds, the length of the leaf, thin, with diſtant villoſe ſcales, two-ſtamened or three-ſtamened. Female catkins ſhorter than the leaf, with few, biggiſh, cluſtered capſules. On the male ſhrub, the branches are more ſlender and lengthened out; the leaves are ſmaller, with more frequent imbricate ſerratures.

Native of Ruſſia, in watery places throughout the temperate and ſouthern parts to the limits of Caucaſus [t].

29. This is a ſhrub, with the branches not much more than a finger's length and proſtrate. Leaves pointed, rounded or emarginate, thick and rigid; when fully grown ſmooth on both ſides, but marked with a network of veins, whence the name: three ariſe from a bud, ſupported each on a footſtalk. Stipules none. Male catkin moſtly terminating, rather woolly, an inch long, on a long ſlender peduncle: ſtamens two: nectary double. Female catkin terminating, ſeldom more than one on a branch, cylindrical, rather longer than the male, on a very long peduncle [u].

Native of high mountains in many parts of Europe. Northern counties of England, Wales and Scotland: flowering in may.

30. This is a ſmall ſhrub, ſcarcely a foot high, having the ſtature and appearance of *Vaccinium uliginoſum*. The upper branches are purpliſh, the uppermoſt fleſh-coloured. Leaves quite entire, ſmooth and green on both ſides, or a little cinereous beneath, with the edge in old leaves a little bent back; in ſome they are more rounded, in others more lengthened out. Peduncles few, furniſhed with leaves. Stipules none. Germs pedicelled, ſmooth. Flowers yellow, from the ſame bud with the leaves. Fruit commonly purpliſh, with the baſe brown [x].

In Ingria it is a foot or eighteen inches in height, and grows like a little tree, with a trunk often thicker than a ſtraw or reed. The Siberian plant is more tender, ſcarcely a foot high, with a trunk rather more ſlender. Branches alternate, pretty cloſely leafed. Leaves without ſtipules, in form and colour like thoſe of *Vaccinium Myrtillus*, ſome of them bluntiſh: in the Siberian plant more tender and ſmaller, always glaucous beneath. Male aments half an inch long, villoſe, with ſmall leaves on the peduncle, long ſtamens, and floſcules thin ſet. Female capſules few, ſmooth, on longer peduncles. In the eaſtern part of Siberia, in a lower ſituation, it grows higher, and has longer looſer catkins [y].

Villars thus deſcribes his *caeſia*, which is ſuppoſed to be the ſame with this, though he himſelf refers it to the *glauca* of Linneus. Height three or four feet. So like *S. Helix*, that it would ſeem to be a variety, if we did not examine the fructification. The wood ſupple and hard; the bark aſh-coloured, ſmooth, reddiſh, on the young twigs brown or green. Leaves oblong, elliptic, lanceolate, ſmooth, very entire, glaucous beneath, very even above; the lateral veins very frequent and very open, which is a ſingular character in this ſpecies. Catkins ſmall, elliptic, ſupported by four or five linear leaves, ſlightly villoſe. The ſcales and capſules are alſo a little villoſe.

Native of Sweden and Iceland, Switzerland, the South of France, Ingria and Siberia.—Introduced in 1772, by the right hon. Sir Joſeph Banks, Bart. K.B. It flowers here in may [z].

31. Stems round, long, cinereous, ſmooth. Leaves ſeveral from a bud, ſeſſile, ſmooth on both ſides, ſpreading, half an inch long or more. Flowers from the ſame buds with the leaves.—Native of Japan [a].

32. This is a ſhrub from two to three feet in height. Stems red, ſmooth. Leaves lanceolate, nerved beneath, having a few hairs ſcattered over them above, and clothed with whitiſh hairs on the under ſurface: the lower ones rather blunt, the upper ones ſharper and rather oblong. Stipules none. Male catkin ovate, ſo woolly that none of the ſcales are viſible. Peduncle leafy. Wool longer at the baſe of the petioles [b].

According to Villars it is a creeping and very ſingular ſhrub, with a large twiſted trunk, of a greeniſh aſh-colour; branches ſhort; bark greeniſh or blackiſh on the younger branches, a little villoſe at the end. Leaves lanceolate, quite white with the thick down which covers their ſurfaces. Male catkins oblong, flowers having two yellow ſtamens. Female catkins oblong, with capſules of the ſame ſhape, villoſe, ſhining white almoſt ſilvery; flowers remaining hid under the leaves.

Native of the mountains of Lapland, the Alps and Pyrenees.

33. This is a ſlender ſhrub, often the height of a man and ſeldom exceeding a fathom. Twigs ſlender, pliant, yellow, very ſmooth and ſhining. Leaves ſtiff, without ſtipules, very narrow and ſharp, glaucous beneath. Female catkins below the leaves naked, ſcarcely longer than an inch, upright, with the ſcales not very cloſe. Down very tender, not very long. It differs from *S. roſmarinifolia* in the catkins and ſmoothneſs of the leaves; the colour alſo of the ſhrub is very different, and the leaves are longer. In the ſlenderneſs of the twigs it almoſt emulates the Weeping Willow.

Native of Ruſſia, in the ſands between the ſouthern Volga and the Rhymnus towards the Caſpian ſea, and by the rivers Sarpa and Cuma very abundant [c].

34. This is a ſhrub, a few feet high, ſometimes growing up to be a ſmall tree, about the height of a man, (or from a yard to eight feet.) Bark grayiſh, ſmooth, entire. Branches numerous, ſpreading, ſmooth, tough, blackiſh or browniſh. Leaves roundiſh or obovate, ſometimes waved at the edge, blunt or with a ſhort taper point at the end; above dark green and ſomewhat woolly, paler cottony and reticulated beneath; on ſhort, cylindrical cottony footſtalks. The leaves when young are ſoft, even, an inch long; when old rigid, wrinkled, and two inches or more in length. (According to Lightfoot, the leaves are about the ſize of a ſixpence when full grown, not quite round, but obverſely oval, wrinkled with large ſwelling veins, and when young woolly on both ſides; but the pubeſcence wears off in ſome degree from the upper ſide as the leaves grow older.) Stipules (or auricles) two, at the baſe of each leaf-ſtalk, kidney-ſhaped, ſcalloped and toothed. Male catkins upright, ovate, blunt, half an inch long or more, three or four lines broad, on a ſhort peduncle: ſtamens two: nectary ſingle. Female catkins upright or ſpreading, ovate-oblong or cylindrical, blunt, from half an inch to an inch in length, and half as broad, on longer peduncles. It ſometimes flowers a ſecond time in the autumn [d].

Native of Europe, particularly the northern parts, in woods and marſhes; flowering in may. The capſules ripen in june. Mr. Lightfoot ſays it is frequent in woods and hedges in Scotland. Mr. Woodward, that it is frequent about Bungay in Suffolk. The ſhoots are ſlender and tolerably flexible.

35. The branches are covered all over with a white pubeſcence. Leaves ſubovate or roundiſh, quite entire, downy with a long and looſe wool, eſpecially when young, ſo cloſe that the veins are not viſible. Hence the whole tree appears white and villoſe. Stipules none. Two catkins generally come out at the ends of the twigs of the foregoing year; and the capſules are ſmooth [e].

This is a dwarf tree, a ſpan high, from a trunk ſcarcely as thick as the human finger, branching very much and diffuſed: branches ſubfaſtigiate, with a brown bark; the extreme ones covered with a ſilky down. Leaves thickiſh, ſubacute, ſeſſile, very cloſely covered on both ſides with a ſilky pubeſcence. Stipules on the uppermoſt branches ovate-acute, villoſe

[t] Pallas. [u] Hoffmann. [x] Linn. ſuec. and lapp. [y] Pallas. [z] Hort. kew. [a] Thunberg. [b] Linn. ſuec. [c] Pallas. [d] Hoffmann. [e] Linn. lapp. and ſuec.

alſo. Female aments biggiſh, lateral, peduncled, accompanied with one or two leaflets. Capſules white with cotton.

Pallas ſeems to have repeated this under the name of *lanuginoſa*; which he deſcribes as a ſpan high or ſcarcely larger, with a ſlender trunk divaricating into branches, and a yellow bark: the younger twigs pubeſcent. Leaves ovate-lanceolate, quite entire, tender, pale green, and clouded on both ſides with a very tender lanugo, ſo that Linneus has ill named it *lanata*. Under this he refers to Linneus. In his *lanata*, which he has figured, he gives no reference; and ſays it is very diſtinct from *caprea* and *acuminata*, but very nearly allied to *fragilis* [f].

Native of the mountains of Lapland, &c.

The *lanata* of Lightfoot is not the *lanata* of Linneus; Dr. Smith names it *ſphacelata*.

β. *S. depreſſa*, which Linneus made a diſtinct ſpecies in Flora lapponica and ſuecica, in Species plantarum is conſidered as a variety of *lanata*.—In the leaves it approaches very near to *S. caprea*, but they are more compact. It does not grow up into a tree, but cloſe to the ground, ſpreading all round ſcarcely a ſpan in length. The bud is a valve deeply emarginate. Catkin from the ſame bud with three leaves, white with curled woolly hairs, and the ſcales brown at the tip.—Native of the mountains of Lapland [g].

36. This approaches ſo near to *S. arenaria*, that perhaps it is only a variety; differing from it in having the upper ſurface of the leaves more villoſe, the leaves themſelves longer and waved.—In habit it approaches very near to *S. glauca*. The leaves are tomentoſe on both ſides, but underneath more ſo. The peduncles are furniſhed with leaves. The germs are hirſute with white cotton. This, together with *Betula nana* ſupports the perpetual fire of the Laplanders [h].

It grows to the height of a man, with a ſmooth ſtem, pale fleſh-coloured or ruſſet, the young twigs white with hairs. Leaves alternate, wrinkled along the veins. The capſules are covered with a white and very thick pubeſcence.

Native of Lapland, where it abounds in all the vallies of the high mountains [i]. Probably alſo native of Ruſſia. Perhaps of Switzerland. Not of Scotland, Lightfoot's *S. lapponum* being the *arenaria* of Linneus.

37. A ſhrub the height of a man. Stems upright, little branched, cinereous or red. Leaves alternate, erect, thick, green above, wrinkled along the veins, and having very fine ſcarcely viſible villoſe hairs thinly ſcattered, beneath ſnow-white, covered thickly with hairs and nerved [k]. Catkins both male and female ovate, very frequent from the leaf-buds: male very villoſe with diandrous flowers; female ſubvilloſe, the glumes terminated by a brown ſtigma.—Gærtner thus deſcribes the fruit—Capſule ovate-beaked. Seeds from eight to ſixteen, crinite all over, with ſilky-white ſimple hairs, the length of the capſule: faſtened to the inner ſurface of the valves, in an erect poſition.

Mr. Lightfoot deſcribes it, under the name of *S. lapponum*, as a ſhrub four or five feet high; the bark ſmooth and reddiſh, the young twigs white and hoary. Leaves alternate, lanceolate and entire, very woolly on both ſides, but moſtly on the under ſide; about an inch and quarter long, and half an inch wide: the longitudinal nerve ſometimes divides the leaf unequally, and the edges are often ſlightly waved. The capſules are covered with a thick woolly down. The upper ſurface of the leaves, when old, loſes moſt of its down, and becomes of a dark green colour.

Monſ. Villars deſcribes it under the name of *S. helvetica*. Height from one to two feet, with a greeniſh bark, but yellowiſh on the branches. Leaves lanceolate, quite entire, thick, netted, very dark green above, ſnow-white beneath; the veins however are viſible through this pubeſcence, which is very fine; the upper ſurface of the leaves is not deſtitute of this pubeſcence, but it is diſtinct and makes little alteration in the colour. Male catkins oblong, diandrous, about an inch long: females attain an inch and half; ſcales and capſules villoſe, ſilky.

The *arenaria* of Lightfoot is diſtinct both from *arenaria* and *lapponum* of Linneus; Dr. Smith names it *argentea*. Mr. Lightfoot thus deſcribes it.—This ſpecies is an humble diffuſe proſtrate ſhrub, ſeldom above two feet high. Leaves of a thick ſubſtance, alternate and elliptical, the largeſt an inch long, and half an inch wide, the ſmalleſt three quarters of an inch long, and a quarter of an inch wide. They are covered with white ſilken hairs on both ſides, but particularly on the under ſide. The dark green colour of the upper ſurface appears through the hairs, as Villars deſcribes in his *helvetica*. At the baſe of the leaves are ſometimes found ſmall ſtipules; but they are generally without them. The ſcales and capſules are hoary.

Native of Scotland, on the ſea ſhores, among blowing ſand.

Arenaria is native of many parts of Europe.

38. This reſembles the preceding, but differs from it in the leaves, which in that are rather ovate, in this rather lanceolate; in that having hairs irregularly ſcattered over the upper ſurface, in this quite ſmooth; in that, the lower ſurface white-tomentoſe, in this, having contiguous white hairs; in that, by no means ſhining, in this ſhining like ſilk. The branches alſo in that are red, in this whitiſh-green [l].

Native of Sweden, and perhaps ſome other parts of Europe, if the ſynonyms be right. Pallas ſays that it is found in the wet paſtures of northern Ruſſia; that it is frequent in ſome parts of Siberia, ſcarcely an ell in height; that it abounds in the marſhes of Ingria, where it is quite a dwarf; and that Gmelin's ſpecies, vol. 1. 162. n. 17. does not ſeem to differ from this.

Introduced in 1775, by the Doctors Pitcairn and Fothergill [m].

39. The true creeping Willow, for it has been much miſtaken, has a very ſtrong woody root, dark brown or black, throwing out many proſtrate or widely ſpreading ſtems, of which the flowering branches are generally erect. Leaves lanceolate or elliptical, ſilky when young, and ſeldom quite ſmooth beneath, when old; without ſtipules. Catkins not long; ſcales obtuſe, hairy. Germ oval, ſilky, with a ſhort undivided ſtyle, and a yellow ſpreading ſtigma, cloven almoſt equally into four lobes. Capſule, when ripe, ſmooth, lanceolate. The ſtyle and ſtigma muſt be particularly noticed in diſcriminating ſome of theſe ſmall Willows [n].

Linneus deſcribes the ſtem as being the thickneſs of the human finger; the branches rod-like, decumbent; the branchlets with ſcattered white hairs. Leaves ovate or ovate-oblong, quite entire, ſmooth on both ſides, glaucous beneath, petioled. Stipules none. The loweſt leaves oppoſite, tranſverſely and little hairy. Catkins lateral. Capſules of the female rufeſcent [o]. This is the leaſt of all the common Willows, indeed ſcarcely larger than *S. herbacea*, being immerſed in the marſh, ſo that only the tops of the branchlets appear [p].

Hoffmann, deſpairing of reconciling the ſynonyms of various authors, has given this ſpecies the name of *depreſſa*, not intending by it however the *depreſſa* of Linneus.

Native of many parts of Europe. Almoſt every moiſt ſandy heath abounds with this Willow, which flowers in may, and ripens its fruit in june and july; when, as in moſt of this genus, the leaves arrive at their full ſize. The varieties are numerous, differing in the breadth of their leaves, and in the greener or browner colour of the whole plant; hence Hudſon and others thought they had diſcovered *S. fuſca* and *roſmarinifolia* among them, whereas the former is *S. arenaria* of our Britiſh writers, but not of Linneus, and the latter is not of Britiſh growth. Profeſſor Gouan of Montpellier miſtook a widely different and nondeſcript ſpecies for *S. repens* of Linneus [*].

40. This is a very low ſhrub, for the moſt part procumbent, and creeping. Leaves very ſmall, alter-

[f] Pallas roſſ. [g] Linn. ſuec. [h] Idem. [i] Linn. lapp. [k] Idem.

nate,

Digitized by Google

ſtate, almoſt ſeſſile, blunt, ſmooth and dark green above, beneath glaucous with a few ſilky-white hairs. Bud one-valved, two-parted. Flowers peduncled, at the end of the branchlets of the year preceding; they are very many, with brown ſcales, and yellow filaments and anthers. The catkins have no leaves, and commonly turn black [q].

The ſilkineſs on the back of the leaves vaniſhes with age. The readieſt mark of diſtinction betwixt this and the preceding ſpecies, is that the catkins are on the ſides of the branches in that, and terminating in this [r].

Linneus remarks that theſe ſmall Willows, *arenaria*, *incubacea*, *repens* and *fuſca* are cloſely allied.

Native of ſeveral parts of Europe. In Britain, by Landown caſtle, between Southampton and Winchester, between Kilnſay and Arncliff in Yorkſhire, and in Scotland.

41. Leaves linear, acute, beneath ſhining, ſilky, villoſe. Stipules none [s].—Native of Sweden, Switzerland, Ruſſia, &c.

42. This occurs with taller and lower ſtems, with thicker ſhoots, yellow or browniſh. Leaves hoary above, ſilvery beneath. Stipules none on adult plants. Catkins among the leaf-buds, ſeſſile, naked: males an inch long, more ſlender than a ſtraw, pale-villoſe. In the autumn the leaves become very long, with a ſubrepand margin, and almoſt naked above.—This ſpecies, which approaches nearer to *viminalis* than to *caprea*, is conſidered by Linneus as a variety of the latter.—Native of Dauria [t].

43. This is a ſhrub the height of a fathom in the water, but in a drier ſituation it becomes a tree, with a trunk the ſize of the human arm. Shoots thick, rather brittle, ſtiff and upright, of a greeniſh gray colour. The younger leaves are ovate-lanceolate, ſilky-ſilvery; the older ones oblong and acute, often more than a great ſpan in length, ſoft, beneath very much veined and hoary. Stipules for the moſt part none, but on the luxuriant branchlets linear-acute. Catkins from the lateral buds, on a peduncle with a few ſmall leaves on it: males an inch and half long, hirſute, with cloſe ſcales, and very long ſtamens; females ſhorter, with the capſules biggiſh, frequent, white with nap. It bears a great affinity to the preceding, but yet it ſeems diſtinct. Perhaps it is allied to *S. ægyptiaca* of Linneus.

Native of Ruſſia, in the ſandy ſhallows and iſlands of the ſouthern Volga, between Zarizin and Aſtrachan; where it does not unfold its buds and put forth its catkins till the beginning of june, when the river begins to ſubſide, a little later than *S. pentandra*.

44. This is a ſmall tree, almoſt like *S. fuſca*, with a trunk the thickneſs of a ſwan's quill, lying on the ground, with a few thickiſh ſtraddling branches a finger's length, quite from the bottom, the bark of which is of a yellowiſh bay colour. Stipules none. Leaves biggiſh in proportion to the plant, thickly netted, above ſhining, very finely villoſe beneath, petioled. Female catkin large, two inches long, the thickneſs of the little finger, on a long peduncle from the ſide of the branches, accompanied by two or three biggiſh leaves. Capſules cluſtered, thickiſh, conical, tomentoſe-hoary on the outſide. It grows within the Arctic Circle, by the Icy Sea.

45. Twigs yellow, ſtraight, little branched, rod-like; the younger ones hoary with nap, frequently all over. Leaves frequent, alternate, on ſhort petioles, ſubſerrate with few and very obſcure toothlets, much nerved, in ſome white-tomentoſe on both ſides, in others beneath only, and ſometimes without any pubeſcence. Stipules permanent, very ſharp, with a toothlet or two. On the banks of rivers it grows like a tree a fathom high or more, with very ſmooth leaves, and very branching twigs of a full yellow and as it were poliſhed; without any ſtipules: but in moiſt open vallies it becomes rod-like and tomentoſe.

Native of the farther Siberia by the ſubalpine ſtreams of the Jeniſea, eſpecially about Karyſch, and in the wet ſubalpine plains of Dauria [u].

46. This not unfrequently becomes a large tree. Branches when young paliſh, downy. Leaves ſlightly tapering to a point at both ends, above green and ſcarce ſenſibly downy, underneath pale green with a very thin woollineſs: edge marked with ſome notches which are ſcarcely apparent unleſs carefully examined, but from the middle downwards evidently waved [x]. The lower buds produce leaves, the upper ones catkins not leafy [y].

Bark aſh-coloured, cracks very fine. Leaves roundiſh, ovate, obovate or ovate-oblong, four or five inches long, about three broad, ſmooth or downy above and dark green; blueiſh gray and cottony on the back, and marked with a network of veins. Stipules only to the uppermoſt leaves, roundiſh and finely ſcalloped. Male catkins ovate-oblong, one or two inches long, often an inch broad, on ſhort peduncles, which are woolly, furniſhed with eight or twelve leaflets, in a double or triple ſeries; the upper flowering firſt: ſtamens two: nectary one. Female catkins oblong or cylindrical, from one to two inches or more in length, half an inch broad, on peduncles which have ſix or ſeven leaflets.—Gleditſch found on this ſpecies both male and female flowers, and others that were hermaphrodite [z].

Our common Sallow was generally ſuppoſed to be this ſpecies; but it is now known to be the *cinerea* of Linneus.

Linneus ſays, that no ſpecies of Salix requires ſuch a dry ſoil as this does. The bark is uſed in dyeing leather by the Laplanders; and the beſt gloves are prepared with it in Scania. The wood is ſoft, light and flexible, fit for ſeveral uſes of the turner, the handles of tools, knife-boards, &c. [a] The coal is eſteemed good for making gunpowder, and is uſed in drawing. It is of conſiderable ſervice to bees, both on account of its flowering early, and having a great abundance of anthers [b].

47. This is a ſhrub ſix feet high, often reſembling a ſmall tree: bark ſmooth, aſh-coloured: branches numerous, upright but diffuſed. Leaves ovate-oblong or ovate-lanceolate, entire or a little ſerrate, two inches long and nearly one broad; thoſe on the lower branches a little ſcalloped at the edge, dark green above with little or no pubeſcence, cottony on the back, pale or glaucous and reticulated. Stipules kidney-ſhaped, waved and toothed at the edge, ſeldom found on the upper leaves. Male catkins ovate or ovate-oblong, an inch or more in length, half an inch broad, blunt, on a peduncle about two lines long, having four or ſix lanceolate ſcales: ſtamens two: nectary one, bellying below, with a ſlender tapering neck, truncate at the end. Female catkins the ſize and ſhape of the other, but on longer peduncles [c].

Linneus has made this a variety of the *caprea*, from which, according to Pallas, it is altogether different, and may eaſily be diſtinguiſhed, by having the leaves leſs wrinkled and veined, more acuminate, more tender, and whitiſh underneath with a very tender nap.

According to Hoffmann, it is an intermediate ſpecies between *caprea* and *aurita*, but different from both.

Native of ſeveral parts of Europe, flowering in march and april: the capſules ripen in may. It was firſt obſerved in England by William Sherard; and is frequent about Oxford. Dr. Withering marks it at Kirkſtall abbey in Yorkſhire.

48. This is allied to *caprea*. Leaves obovate-oblong, above wrinkled and ſmooth, beneath tomentoſe and aſh-coloured. Capſules ſmooth, pedicelled.—Native of the kingdom of Tunis [d].

49. Native of Pennſylvania. Mr. William Young. Introduced in 1765. It flowers in april [e].

50. The Oſier is a very tall ſlender obſequious quick-growing ſhrub. Leaf and flower-buds diſtinct as in *S. caprea*. Leaves rolled back at the edges before they unfold [f].

Frequently

Digitized by Google

Frequently arboreſcent. Bark grayiſh, ſmooth, with here and there a crack. Branches very long, ſtraight, ſlender, tough. Leaves, eſpecially the lower ones, a ſpan long or more, waved at the edge. Male catkins ovate or oblong, from an inch to an inch and half in length, three or four lines in breadth, on very ſhort peduncles: ſtamens two: nectary one. Female catkins ovate-oblong or cylindrical, of the ſame length with the male, half an inch broad; peduncle two lines long. The leaves being ſilvery underneath; the nectary in the male flower being long and ſlender; and the ſtyle in the female flower being very long, are ſufficient marks to diſtinguiſh this and its varieties from the other ſpecies [g].

Leaves above deep ſhining green, underneath grayiſh, cloſely beſet with very fine ſhort hairs lying cloſe to the ſubſtance of the leaf. Leaf-ſtalks about half as long as the breadth of the leaf. A ſmall tongue-ſhaped glandular ſubſtance fixed to the ſtem juſt above the inſertion of the leaf-ſtalk, in the upper part of which there is a hollow to receive it. Leaf-ſcales (ſtipules) minute, one on each ſide of the baſe of each leaf-ſtalk [h].

Mr. Lightfoot remarks, that the nerves of the leaves underneath are parallel, but diverge almoſt to right angles with the midrib; that the edges are either ſlightly toothed or undulated, but being turned back this is ſcarcely perceptible; that at the baſe of the leaves, eſpecially near the top of the twigs, there are generally ſome linear awl-ſhaped ſtipules; that the catkins are ſeſſile, cylindrical, and ſhorter than the leaves; that the ſcales are oval and fuſcous, and the capſules downy. He notes a variety, the leaves of which on the under ſide are of a paler green than the upper, but without any viſible hoarineſs.—Some of the above remarks are from Haller.

This is the true *Oſier*, ſays Ray, at leaſt ſo called in Eſſex and Cambridgeſhire.—Varieties of it, and different ſpecies are doubtleſs cultivated under this name.

Native of moſt parts of Europe, in moiſt boggy land, woods and hedges. Much cultivated in oſier-holts, for making hoops and the larger ſorts of baſkets, hampers, cradles, bird-cages, &c. It is planted to prevent the banks of rivers from being waſhed away by the force of the current; and it forms a hedge very uſeful in keeping off winds [i].—Putcheons and weels for catching eels are made of the twigs [k].

Evelyn enumerates many varieties of Oſier known among baſket-makers in his time. We have in England, ſays he, three vulgar ſorts: one of little worth, being brittle, and very much reſembling the Sallow, with reddiſh twigs, and more greeniſh and rounder leaves. A ſecond, called *Perch*, of limber and green twigs, having a very ſlender leaf. The third totally like the ſecond, only the twigs not altogether ſo green, but yellowiſh. This is the very beſt for uſe, tough and hardy. The moſt uſual names by which baſket-makers call them about London are, the *Hard-Gelſter*, the *Horſe-Gelſter*, *Whyning* or *Shrivelled-Gelſter*, *Black-Gelſter* in which Suffolk abounds. Then follow the *Goldſtones*, the hard and ſoft, brittle and worſt of all the *Goldſtones*; the ſharp and ſlender-topped yellow *Goldſtone*; the fine *Goldſtone*. Then there is the *yellow Oſier*, the *green Oſier*, the *ſnake* or *ſpeckled Oſier*, *Swallow-tail* and *Spaniard*. To theſe we may add, the *Flanders Willow*, which will arrive to be a large tree: with theſe coopers tie their hoops to keep them bent. Laſtly, the *white Sallow*, uſed for green-work; and if of the tougheſt ſort to make *quarter can-hoops*, of which our ſeamen provide great quantities [l].

Innumerable varieties are cultivated in the oſier-grounds for the baſket-makers; and the ſame frequently under different names in different places; ſo that it would be difficult and of little uſe to enumerate them. The Dutch and Wire Oſiers are eſteemed about London. Dr. Smith informs me, that Mr. Crowe has lately made out the true Velvet Oſier, which is a valuable ſort, to be diſtinct from *viminalis*.

51. In woods more than ſix and ſometimes near twelve feet high; in expoſed boggy ground it ſpreads more, but does not riſe ſo high. Leaves alternate, rude, rugged, wrinkled and green above, beneath rough with hairs, the veins indiſtinct, the edge ſerrate, on looſe petioles two lines in length. Stipules in ſhape of half a heart, on each ſide ſerrate with three glands. Catkins browniſh, placed below the leaves, on a peduncle with a few ſmall ſpear-ſhaped leaflets [m].

Branches tough, cylindrical, ſmooth, reddiſh. Leaf-ſtalks conſiderably ſhorter than half the breadth of the leaves, nearly cylindrical, with a gland on each, juſt above the baſe. Stipules minute on each leaf, at the baſe of the foot-ſtalk. Catkins ovate, an inch and quarter long, and three quarters of an inch wide [n].

The young twigs whitiſh and downy. Leaves variouſly ſhaped even upon the ſame branch, ſome acute, others obtuſe; they are generally ſlightly ſerrate towards the upper part, and undulated towards the baſe; their upper ſurface is downy at firſt, but afterwards ſmooth, or the veins at moſt only hairy; the under ſurface wrinkled, hoary, ſoft and downy. Catkins cylindrical, ſhort and thick. Capſules downy at firſt, but when ripe almoſt ſmooth.

The inhabitants of the Highlands and Hebrides frequently uſe the bark to tan leather. The wood is ſmooth, ſoft, white and flexible. It is often uſed to make handles for hatchets, prongs, ſpades, &c. and furniſhes ſhoemakers with cutting-boards, and whetting-boards to ſmooth the edges of their knives upon [o].

About Palm Sunday, the children, in many parts of our iſland, gather the flowering branches, calling them Palms [p].

This is our common Sallow, and Engliſh botaniſts took it for the *caprea* of Linneus, till they were taught better by Mr. Aſzelius, and by conſulting the Linnean herbarium.

Native of Europe in moiſt woods and hedges, not in a dry ſoil. It flowers in april [q].

52. The common or White Willow, when ſuffered to grow without lopping, becomes a large and lofty tree. It is quick of growth, and when lopped ſoon decays. The trunk is ſtraight with a gray rough bark full of cracks. Branches numerous, upright but diffuſed, gray or browniſh green, the upper ones often duſky red. The inner bark is green; whereas in *vitellina* it is yellow, and in *babylonica* purple. Leaves ſharply and elegantly ſerrate; ſhining but pubeſcent above, white and ſilky underneath. Male catkins cylindrical, blunt, from an inch and half to two inches in length, four lines in breadth, on peduncles half an inch long. Stamens two. Nectaries two, one before the ſtamens obcordate, the other behind them oblong. Female catkins ſlender, cylindrical, two inches long, three or four lines broad, on peduncles near an inch in length [r].

Native of Europe. It flowers in april and may, and the capſules ripen in june. It loves a moiſt and open ſituation.

The wood is white, light and tough. Hanbury ſays, it is agreeable to burn, becauſe it does not ſmoke, and gives a regular heat; it is not however generally eſteemed for the fire. The old branches are brittle, the young ones pliant.

The bark will tan leather, and dye yarn of a cinnamon colour. The inner bark has afforded a miſerable ſubſtitute for bread to the neceſſitous inhabitants of Kamtſchatka.

The wood is uſed for poles, ſtakes, hoops, &c. Cattle will feed on the leaves. The Arabs diſtil their celebrated *Calaf* water from the catkins of any ſpecies in which they are fragrant. They uſe this water as a cooling beverage, or as a febrifuge. In the ſummer ſeaſon the leaves have been obſerved to diſtil a clear liquor, which Scopoli affirms to be owing to the liquefaction of the ſpume (cuckoo-ſpittle, vulg.) which envelops the *Cicada ſpumaria* [s].

Mr. Stone (in Philoſ. Tranſ. 53. 195.) gives an account of the great efficacy of the bark of this tree in

[g] Hoffmann. [h] Withering. [i] Linn. ſuec. Withering. [k] Stokes in Withering. [l] Silva, b. 1. c. 19. § 17. 19.

[m] Linn. ſpec. ſuec. lapp. [n] Withering. [o] Lightfoot. [p] Stokes. [q] Withering. [r] Hoffmann. [s] Lightfoot.

curing

Digitized by Google

curing intermitting fevers. He gathered the bark in ſummer, when full of ſap, dried it by a gentle heat, and gave a dram of it powdered every four hours between the fits. In a few obſtinate caſes he mixed it with one fifth part of Peruvian bark. It is remarkable that intermittents are moſt prevalent in wet countries, and this tree grows naturally in ſuch ſituations. Whilſt the Peruvian bark remained at its uſual moderate price it was hardly worth while to ſeek for a ſubſtitute; but now its price is ſo great, and the ſupply from South America hardly equal to the conſumption, we may expect to find it more adulterated every year. The white Willow bark is therefore likely to become an object worth the attention of phyſicians, and if its ſucceſs upon a more enlarged ſcale of practice ſhould prove equal to Mr. Stone's experiments, the world will be much indebted to that gentleman for his communication. The bark of *S. triandra, fragilis*, &c. have the ſame properties. (See triandra, n. 2. fragilis, n. 13. and Helix, n. 16.) A ſet of experiments ſhould therefore be inſtituted to aſcertain which of the ſpecies ought to be preferred[t].

53. Trunk erect but ſhort, as thick as a man's body; with a large and very branching head; the branchlets are rod-like. Leaves alternate, broad-lanceolate, acuminate, moſt minutely ſerrate, ſmooth above, whitiſh beneath, from two to four inches long, on ſhort petioles. Male catkin filiform; its peduncle often leaf-bearing, iſſuing from the dry ſmooth brown involucre-like ſcales of the bud. Filaments ſix to eight, retrofracted: anthers twin, ſingly orbicular and grooved. Female catkins ſhorter than the male. Germ on a long pedicel: ſtyle of the ſame length with the capſule; with two ſpreading ſtigmas. Capſule heart-ſhaped, opening from the apex, one-celled, four-ſeeded. Seeds oblong, involved in much fine white cotton, which does not adhere to them, but is inſerted with them into the bottom of the capſule.

This is the only ſpecies of Willow yet found in India. It is a middle-ſized tree, growing on the banks of rivulets and in moiſt places far among the mountains. It flowers in the cold ſeaſon[u].

There are other ſpecies of Willow not yet ſufficiently aſcertained; and many varieties which are well known and have diſtinct names among thoſe who cultivate them for uſe. The Mountain, Upland or Red Willow, and the Huntingdon Willow, for the propagation of which premiums are offered by the Society of Arts, Manufactures and Commerce, I am not able to reduce to their proper ſpecies.]

There are ſome other ſorts of Willows which are planted in the oſier-grounds, and are diſtinguiſhed by the baſket-makers and dealers in them, under titles which they have applied to them, which are little known to others; theſe are annually cut down, and always kept low, but when they are not cut down, and have room to grow, will riſe to a conſiderable height, and ſome of them will become large trees; ſo that they may be planted for the ſame purpoſes as the White Willow, and will make a variety when intermixed with it, though they are commonly cultivated for their twigs, which produce good profit to the owner of the land.

PROPAGATION AND CULTURE.

All the ſorts of Willows may be eaſily propagated by planting cuttings or ſets, either in the ſpring or autumn, (but the ſpring is the ſureſt ſeaſon) which readily take root, and are of a quick growth. Thoſe ſorts which grow to be large trees, and are cultivated for their timber, are generally planted from ſets; which are about ſeven, eight or nine feet long; theſe are ſharpened at their larger end, and thruſt into the ground two feet and a half by the ſides of ditches and banks, where the ground is moiſt; in which places they make a conſiderable progreſs, and are a great improvement to ſuch eſtates, becauſe their tops will be fit to lop every ſixth or ſeventh year. This is the uſual method now practiſed in moſt parts of England, where the trees are cultivated, as they are generally intended for preſent profit; but if they are deſigned for large trees, or are cultivated for their wood, they ſhould be planted in a different manner; for thoſe which are planted from ſets of ſeven or eight feet long always ſend out a number of branches towards the top, which ſpread, and form large heads fit for lopping, but their principal ſtem never advances in height; therefore, where regard is paid to that, they ſhould be propagated by ſhort young branches, which ſhould be put almoſt their whole length in the ground, leaving only two or at moſt but three buds out of the ground; and when theſe have made one year's ſhoot, they ſhould be all cut off, except one of the ſtrongeſt and beſt ſituated, which muſt be trained up to a ſtem, and treated in the ſame way as timber trees. If theſe are planted with ſuch deſign, the rows ſhould be eight feet aſunder, and the ſets four feet diſtance in the rows, by planting them ſo cloſe, they will naturally draw each other upward, and, when they are grown ſo large, as to cover the ground and meet, they ſhould be gradually thinned, ſo as at the laſt to leave the rows about twelve feet aſunder, and the plants in the rows eight. If they are ſo treated, the trees will grow to a large ſize, and riſe with upright ſtems to the height of forty feet or more.

When theſe cuttings are planted, it is uſual to ſharpen thoſe ends to a point which are put into the ground, for the better thruſting of them in; but the beſt way is to cut them horizontally juſt below the bud or eye, and to make holes with an iron inſtrument in the ground where each cutting is to be planted, and when they are put in, the ground ſhould be preſſed cloſe about the cuttings with the heel to ſettle it, and prevent the air from penetrating deep into the ground.

The after care muſt be to keep them clear from weeds the two firſt ſeaſons, by which time they will have acquired ſo much ſtrength, as to over-power and keep down the weeds; they will alſo require ſome trimming in winter to take off any lateral ſhoots, which, if ſuffered to grow, would retard their upright progreſs.

There are great tracts of land in England fit for this purpoſe, which at preſent produce little to the owners, and might, by planting of theſe trees, turn to as good account as the beſt Corn land. The larger wood, if ſound, is commonly ſold for making wooden heels for ſhoes; as alſo to turners for many kinds of light ware.

The Sallows are commonly planted in cuttings made from ſtrong ſhoots of the former year, about three feet long; theſe are commonly thruſt down two feet deep into the ground, and are one foot above it. The cuttings ſhould be placed about five feet row from row, and two feet aſunder in the rows, obſerving always to plant the rows the ſloping way of the ground (eſpecially if the tides overflow the place;) becauſe, if the rows are placed the contrary ways, all the filth and weeds will be detained by the ſets, which will choak them up.

The beſt ſeaſon for planting theſe cuttings in the oſier-grounds is february, for if they are planted ſooner, they are apt to peel, if it proves hard froſt, which greatly injures them. Theſe plants are always cut every year, and, if the ſoil be good, they will produce a great crop; ſo that the yearly produce of one acre has been often ſold for fifteen pounds, but ten pounds is a common price; which is much better than Corn land; ſo that it is great pity theſe plants are not more cultivated, eſpecially upon moiſt boggy ſoils, upon which few other things will thrive.

[In order to raiſe a bed of Oziers, the ground being properly dug over or ploughed, cuttings muſt be procured of two year's wood, though the bottom parts of the ſtrongeſt one year ſhoots may do; they ſhould be two feet and a half long, a foot and half to be thruſt into the ground, and the other foot to remain for the ſtool: put them in at two feet diſtance every way. The firſt ſummer the weeds muſt be kept under, and the next the talleſt muſt be hacked down. In three years the ſets ſhould all be cut down to the firſt-planted head. They will ſell well to the hurdle-maker; and there will be a regular quantity of proper ſtools for an annual crop of twigs, which will be worth five

[t] Withering, p. 56. [u] Roxburgh.

Digitized by Google

five or ſix pounds, or more, an acre, for the baſket-maker.

If oſier-holts are overflowed by the tide, the rows ſhould go the ſame way with the ſtream, and ſhould be at a greater diſtance from each other, that the weeds, &c. may have free courſe; in this caſe the cuttings may be planted cloſer in the rows.

Plantations deſigned to be cut every ſix or ſeven years for poles, may be raiſed in the ſame manner; only that the cuttings muſt be a yard aſunder: but when intended for hurdles, the diſtance need not be ſo great.

In oſier-holts they commonly mix with the true Oſier, the Sallow, the long-ſhooting green Willow, the Crane Willow, the Golden Willow, the Silver Willow, the Welſh Wicker, &c. for different purpoſes of the baſket-maker.

For timber, the cuttings ſhould be of the laſt year's ſhoot; a foot and half long, a foot of which ſhould be thruſt into the ground: they ſhould be planted at the diſtance of three feet every way. The end of may, or the beginning of june, the ſets that have ſhot too luxuriantly ſhould have all the branches removed, except the leading ſhoot [x].

In planting Willows, where the ground is too wet, or ſubject to be flooded, lay it out in beds three or four yards wide, with a ditch on each ſide, three feet wide at top, and one foot at bottom, two feet and a half deep, throwing the earth out of the ditch upon the bed: there ſhould be a yard of earth above the common level of the water.

The ſets or truncheons ſhould be from twenty inches to two feet in length. Dibble them in by an iron crow fourteen or twenty inches, ſo that not more than ſix, nor leſs than four inches appear above.

The cuttings ſhould be from poles of three years growth. Set them three feet aſunder, in a quincunx order. The time of planting from january to the end of march. The ſets ſhould be cut from december to the end of february.

The late Mr. Bakewell had different ſmall plantations of the Dutch Willow, one of which he uſed to cut down annually at ſeven years growth; they ran very long, and ſome of them very large, and were ſplit and uſed for poſts, gates, rails, &c. for which they are very excellent. He uſed no other wood for thoſe purpoſes.

The Oſier, ſays Mr. Marſhall, in low moiſt ſituations, may be cultivated, on a ſmall ſcale at leaſt, with great advantage to every farm, for binders, thatching rods, hurdles, edders, ſtakes, rake and ſcythe handles, &c. and for poles and rails of almoſt any length.

The firſt ſtep is to throw the ſoil into beds, ſo as to lay the ſurface ſufficiently dry; the Oſier diſliking an unſound ſituation.

This work ſhould be done in autumn: and in march following, theſe beds being firmly eſtabliſhed, and their ſurfaces in good working order, the ſoil ſhould be thoroughly trenched with the ſpade, and truncheons inſerted.

Put in the ſets two feet from each other, dibbling in a Potatoe plant between them. During ſummer keep the ſurface clean hoed, and the Potatoes earthed up.

In autumn, after the Potatoes are taken up, draw the ſoil towards the roots of the plants, leaving channels between them, to carry off the winter's rains. The enſuing ſpring look the plants over, and replace ſuch as have failed with freſh ſtrong ſets.

After this, little more will be neceſſary than to keep down the taller weeds: if however the plants do not overcome the weeds in the courſe of three or four years, they muſt be cut down to the ſtub, the ſpaces dug, the rubbiſh turned in, and the roots of the plants freed from incumbrances, with the hoe.

Notwithſtanding the Oſier is uſually planted near water, it affects a ſound, if not a dry ſoil. The places it moſt delights in are drained moors, and the banks of large rivers, both peculiarly dry ſituations: it has no diſlike to being flooded occaſionally, but ſeems to be invigorated by ſuch irrigation: the ſand banks therefore which are frequently thrown up by the ſides of rivers, and ſometimes lie for half a century before they become profitable, are peculiarly eligible to be converted into Oſier-grounds.

The method of planting an Oſier-ground is this: the ſoil being laid perfectly dry, and its ſurface made clean; cuttings of the ſecond or third year's growth, and about twelve inches long are planted in drills, about two feet and a half aſunder, in the month of march. The cuttings ought to be thruſt in ſeven or eight inches deep, leaving four or five inches of head above ground.

The intervals ſhould be kept ſtirred with a ſmall plough; or the firſt year, a crop of Potatoes may be taken; the drills in either caſe muſt be kept perfectly clean with the hand-hoe; and at the approach of winter, the intervals ſhould be ſplit, and the mould thrown to the roots of the young plants, to lay them dry and warm during winter. The following ſpring the firſt year's ſhoots may be trimmed off, and the plants which have failed muſt be replaced.

The ſecond ſummer, the intervals muſt be kept ſtirred, the drills hoed, and the plants earthed up, as before, againſt winter.

The enſuing ſpring, the ſtools muſt again be cleared; although the twigs as yet will be of little value. But at the third cutting they will produce marketable ware, and will increaſe in quantity and value, until the profits ariſing from them will be very great. In ſituations which the Oſier affects, and in countries where the twigs are in demand, Oſier grounds have been known to pay an annual rent of ten pounds an acre. Under ordinary circumſtances they will, if properly managed, pay four or five [y].

Willow Pollards, it is well known, are planted with great profit, by the ſides of brooks and rivulets; and might, in many others, be planted with equal benefit.

An error, too frequently committed, in planting Willow poles for pollards, is to ſet them within the banks of the rivulet or brook. The proper ſituation for them is ſome feet, not leſs than half a rod, from the brink of the channel. The roots ſoon reach the moiſture, and afford ſhade to cattle in hot weather, without danger to themſelves, or injury to the channel or its banks [z].

It is generally imagined, ſays Dr. Anderſon [a], that the Willow can be made to thrive no where except in wet or boggy ground. Experience however has ſufficiently convinced me that it will not only grow, but thrive, in any rich well cultivated ſoil, even although it be of a very dry nature.

He recommends it as a fence for dividing any extenſive field of rich ground into ſeparate incloſures. For this he adviſes to mark off the boundaries in winter or early in the ſpring, in order to give a complete fallow to a ridge ſix or eight feet broad, in the middle of which the hedge is intended to be planted the enſuing winter. Plough it frequently during the ſummer; and in autumn manure it well with dung, lime, or both, and form it into a ridge before winter.

Be provided with a ſufficient number of plants previouſly reared in a nurſery as near the field to be incloſed as poſſible; for as they are very bulky, long carriage will be expenſive. Plant as early in winter as can conveniently be done.

All the large kinds of hoop Willows may be uſed for this purpoſe; but there is a ſort with ſtronger and more taper ſhoots, covered with a dark-green bark when young, which, upon the older ſhoots, becomes of an aſh gray, of a firm texture, and a little rough to the touch: the leaves are not ſo long as, but much broader than thoſe of the common Hoop Willow, pretty thick, and of a dark-green colour. This becomes very quickly of a large ſize at the root, and being ſtrong and firm, deſerves to be preferred for this purpoſe.

The ſhoots ought to be of two or three years growth, and ſhould never be leſs than eight or nine feet in length.

Having

Digitized by Google

Having ſtretched a line along the middle of the ridge, put in the ſets at the diſtance of eighteen or twenty inches from one another, ſlanting a little to one ſide, in a direction parallel to the line. Then begin at the oppoſite end of the line, and plant another row in the intervals between the plants of the former row; making theſe incline as much as the others, but in a contrary direction. Then plaiting theſe baſket-wiſe, work them into lozenges, like a net, faſtening the tops by plaiting the ſmall twigs with one another. Thus a tolerably good fence is formed immediately; but as theſe plants directly take root, and quickly increaſe in ſize, it becomes in a few years a very ſtrong hedge.

A man may plant and twiſt about a hundred yards in a day, if the plants be laid down to his hand: and there is no fence which could be reared at ſuch a ſmall expenſe, ſo quickly, and continue ſo long. It will be greatly improved by putting a plant of Eglantine (Sweet-briar or wild Briar) between each two plants of Willow, which will quickly climb up and be ſupported by them, and by its numerous prickles would effectually preſerve them from being browſed upon by cattle. (Brambles would anſwer the ſame purpoſe.)

Keep the ridge in culture for one year at leaſt; ſtir the earth once or twice by a gentle horſe-hoe in the beginning of ſummer, and in the month of june ſow it with Turneps or plant it with Coleworts, which will abundantly repay the expenſe of the fallow.

In lands of indifferent value, divided into ſmall fields, the produce of ſuch hedges would in ſome places amount to the value of the land itſelf. As the Sallows are adapted to wet ſoils, ſo the red mountain Willow will thrive on dry grounds, and on moſt others [b].

Nothing anſwers better againſt brooks, where the water and bank are not a complete fence of themſelves, than the network fence of Willows or Sallows, provided it can be kept from cattle till it has ſufficiently eſtabliſhed itſelf.

Truncheons of live Willow make excellent poſts in new incloſures, as they will often take root and grow, and therefore will not rot, nor be ſubject to the depredations of wood-ſtealers.

DESCRIPTIONS, *&c.*

These plants, so well known for producing alkaline salt, commonly called Barilla, Soda or Kelp, are many of them herbaceous and annual, others have shrubby stems. The leaves are generally alternate, but in some opposite; in some round, in others flat. Flowers terminating or axillary, in some having three bractes at the base[d]. Jussieu is for having the genus divided. Linnæus, in the first edition of his Species Plantarum, placed some of the species under Chenopodium. Haller has selected a few under the title of Lerches.

1. Root annual, fibrous. Stems rigid, pubescent, very much branched, spreading in all directions, and forming a large round bush, almost inaccessible on account of the numerous prickly leaves, which are alternate, spreading, awl-shaped, channelled, dilated at the base, rugged, each tipped with a very sharp spine. Flowers axillary, solitary, sessile, with three bractes, resembling the leaves and thorny, at the base of each. Leaves of the calyx externally dilated into a broad reddish waved margin, internally closely approaching each other, and covering the seed like a capsule. Seed turbinate or top-shaped, with its cotyledons curiously twisted into a spiral form; by which character this genus is essentially distinguished from *Chenopodium*, and all others of the same natural order[e].

Native of the sandy shores of Europe, Asia, Africa and America. It flowers with us in july.

This plant, on being burned, affords fossil alkali, as do many other plants, some in a greater proportion. This contributes more generally to the manufacture of Soda, for making glass than *Chenopodium maritimum*, but is not reckoned equal to some other species of Salsola. See *S. Soda* and *sativa*.

2. Gmelin and Willich esteem this to be a variety of the preceding. Scopoli says, the flowers of this are two-styled. According to Linnæus, the style is trifid in *S. Kali*.] Mr. Miller says that it sends out many diffused stalks a foot and half long; that the leaves are linear, an inch long; that the calyxes are blunt, and not so closely encompassed with leaves as those of the other.

[This affords an ordinary kind of Soda, with which the French frequently mix the better kind in Languedoc. This adulteration is also practised by the Sicilians, who distinguish the plant by the term *salvaggia*[f].

Native of the South of Europe, and of Africa, on the sea coast.]

3. The stalks of this seldom rise more than five or six inches high. The flowers are small, and of a rose-colour, soon fading.—Native of Tartary.

4. [Stems procumbent or upright, with spreading branches. Leaves long fleshy spreading awl-shaped smooth, roundish, widened at the base, ash-coloured, with two opposite longitudinal streaks, the margin of the base membranous and diaphanous. Flowers axillary, sessile, one, two or three together[g].

Native of the South of Europe. Cultivated in 1759, by Mr. Miller[h], with the two preceding.]

He thus describes it: Stems near three feet high, sending out hoary branches their whole length, at bottom spreading out wide, but short towards the top. Leaves on the principal stalk, and on the lower part of the branches, long, slender, without spines; on the upper part of the stalk and branches, short and crooked. At the base of the leaves are produced the flowers, which are so small as to be hardly perceptible. In warm countries it produces the flowers in june, and the seeds ripen in august; but in this country the plants seldom flower. This is the sort which is cultivated in Languedoc for making alkaline salt.

[Mr. Townsend says that the true Barilla is made in Spain from this species; both this and the *sativa*, according to others, are cultivated there for that purpose, but principally the latter.

5. This grows abundantly on the Spanish coast which is washed by the Mediterranean sea, and affords all the best Soda consumed in Europe, and called by us Spanish or Alicant Soda, and by the Spanish merchants *Barilla de Alicante*[i].

In september the Spaniards collect the crop into heaps about six feet in height. Of these they burn fifty in one hole, stirring well the broth with sticks; then, protecting it from rain, at the expiration of eight or ten days, the stone will be cold enough to be removed.

There are several other plants which they burn for pot-ash in Spain, besides *Salsola Soda* and *sativa*. As—
1. Aguaful, a species of Mesembryanthemum.
2. Salicor, which is Salicornia europæa.
3. Barilla punchosa Soda colorada. Salsola Kali.
4. Sosa prima. Chenopodium maritimum.
5. Sosa blanca. Chenopodium album.
6. Sosa gorda. Salsola vermicularis.
7. Sosa lenosa. Salsola rosacea.
8. Hyerba de la plata. Mesembryanthemum crystallinum[k].

In some countries other plants are used for this purpose: as Salicornia arabica, Mesembryanthemum nodiflorum, Plantago squarrosa; all these, according to Alpinus, yield this alkali. It has also been procured from several of the Fuci or sea-weeds, especially F. vesiculosus; and is distinguished here by the name of Kelp. The preparation of this is fully described by Borlase, in his observations on the state of the Islands of Scilly.

Batis maritima is noticed by Jacquin on the coast about Carthagena in New Spain, as having a very salt taste, and as being prepared there into Soda, which is used for the purpose of making glass. The inhabitants call it Barilla.

Various other marine plants yield Barilla or Soda by combustion, but the principal are of this genus or Salicornia, which both derive their names from this circumstance. Salsola Kali, on the authority of Rauwolff, is the sort from which the salt is usually obtained in the eastern countries.

It is to be regretted, that the different sorts of Soda which are brought to European markets, have not been sufficiently analysed to enable us to ascertain with tolerable certainty the respective value of each: indeed whilst the practice of adulterating this salt continues, any attempts of this kind are likely to prove fruitless. The best information on this subject is to be had from Jussieu, Marcorelle and Cadet in Memoires de l'Academie Francoise, Borlase, and Sestini in Lettere della Sicilia.

According to chemical analysis Soda generally contains a portion of vegetable alkali and neutral salts; as common salt, and sometimes vitriolated tartar, or Glauber salt; likewise liver of sulphur; and not unfrequently some portion of iron is contained in the mass: it is therefore to be considered as more or less a compound, and its goodness is to be estimated accordingly.

[d] Jussieu. [e] Smith. [f] Woodville. [g] Linn. and Desfont. [h] Hort. kew. [i] Woodville. [k] Townf. Spain. 3. 197 to 199.

Digitized by Google

cordingly. The Spaniſh Soda of the beſt ſort is in dark-coloured maſſes of a blueiſh tinge, very ponderous, ſonorous, dry to the touch, externally abounding with ſmall cavities, without any offenſive ſmell, and very ſalt to the taſte; if long expoſed to the air, it undergoes a degree of ſpontaneous calcination. The beſt French Soda is alſo dry, ſonorous, brittle, and of a deep blue colour, approaching to black. The Soda, which is mixed with ſmall ſtones, gives out a fetid ſmell on ſolution, and is white, ſoft and deliqueſcent, is of the worſt ſort.

The method of purifying this ſalt for medicine, is directed in the London Pharmacopœia under the article *Natron præparatum*; and in the Edinburgh Pharm. under that of *Sal alkalinus fixus foſſilis purificatus.* The pure cryſtals, thus formed from Alicant Barilla, are colourleſs, tranſparent, lamellated, rhomboidal, and one hundred parts are found to contain twenty of alkali, ſixteen of aerial acid, and ſixty-four of water; but upon keeping the cryſtals for a length of time, if the air be not excluded, the water evaporates, and they aſſume the form of a white powder. This ſalt preſerves fleſh longer than common ſalt, but not ſo long as the vegetable alkali. Natron has been thought uſeful in ſcrophulous diſorders, but is ſeldom given in its ſimple ſtate.

In combination with vitriolic acid this alkali forms Glauber ſalt or Natron vitriolatum; with nitrous acid, cubic nitre; with marine acid, common ſalt; with the ſedative ſalt of Homberg, borax; and with cream of tartar, Rochelle ſalt or ſel ſaignette.

Soda or Barilla is in common uſe in the manufactures of glaſs and ſoap. White Spaniſh ſoap, being made of the finer kinds of olive oil, is preferred for internal uſe[l].

Salſola ſativa was introduced here in 1783 by Abbé Pourret[m].

6. This alſo is a native of Spain.

7. Peduncles three-flowered, the lateral ones ſpringing at the baſe of the middle one, as in *Theſium* and *Turnera.* Styles three[n].

Linneus at firſt made this a *Chenopodium*, and Pallas thinks it rather belongs to that genus.—Native of Italy, Saxony and Aſtrachan. Introduced in 1775, by John Earl of Bute[o].

8. In habit this very much reſembles the preceding, but it is quite diſtinct, having axillary flowers not inſerted into the leaf, as in that.—Native of Spain[p].

9. Stems a foot high, panicled, even, purpliſh, ſomewhat ſtriated. Leaves flat above. Flowers axillary, ſeſſile, in threes. Calyx-leaves very much arched, convex, cloſed, in the fruit hyaline. Styles three, cloven at the top[q].

Linneus had originally made this alſo a *Chenopodium*, and Pallas remarks that it has an affinity to that genus.

Salſola baccata alexandrina is perhaps the ſame with this. It has an upright ſtem, a foot high, hardiſh, with almoſt upright branches; three flowers in each axil; the calyxes, when the fruit is ripe, ſucculent, ſmooth, ſubdiaphanous, ſeſſile, green; and three ſtyles.

Native of Aſtrachan[r].—This, and all the preceding, are annual plants.

It was introduced in 1782, by P. M. A. Brouſſonet, M.D.[s]

10. Stems branched, panicled at the top, branches ſimple covered with little balls of flowers, which appear to be naked, but are propped by a ſhort leaf. Leaves as in the preceding.

Native of the Eaſt Indies, near Tranquebar, on the coaſt[t]. Perennial.

11. Diſtinct from the next ſpecies, in having a ſuffruticoſe ſtem, narrower leaves ſhorter than the flowers. Native of Spain. Perennial[t].

12. Native of Denmark and the South of France, on the ſea coaſt. Diſtinguiſhed by its pubeſcent leaves. It is annual.

[l] Woodville. [m] Hort. kew. [n] Linn. ſyſt.
[o] Hort. kew. [p] Willdenow. [q] Linn. ſyſt.
[r] Linn. mant. [s] Hort. kew. [t] Willdenow.

13. Stem two feet high, when young woolly, but towards the time of fructification becoming naked. Leaves blunt, fleſhy. Flowers in threes, yellow. Calyx growing out into ſharp very long chaffs, with the lateral laminæ roſe-coloured. It differs in its roſe-coloured anthers from all the reſt.—Native of Siberia about Saratſchik[u].

14. This is an annual plant, native of the dry ſalt plains of Siberia.

15. Stems very much branched. Leaves fleſhy, awnleſs. Flowers axillary and terminating, glomerate, ſeſſile. Calyx funnel-form, five-parted, membranous, with a flat, ſmall, coloured border.—Native of the ſea-coaſt of Spain and Sicily[x].

16. Native of Spain, Auſtria, Switzerland and Siberia. Introduced in 1780, by Peter Simon Pallas, M.D.[y]

17. This has the habit of Salicornia or Polycnemum. Native of Siberia by the lake Altan, and in the ſteppes of Aſtrachan. Annual[z].]

18. Stems ſhrubby, three or four feet high, ſending out many ſide branches. Leaves fleſhy, ovate, acute-pointed, coming out in cluſters from the ſide of the branches; they are hoary, and have no ſtiff prickles. The flowers are produced from among the leaves, towards the ends of the branches, they are ſo ſmall as ſcarcely to be diſcerned.—Native of Spain, [and Siberia. Cultivated by Mr. Miller in 1759.

19. Native of the Tartarian ſteppes.

20. This is a ſhrub the height of a man, leafleſs and very irregular. Branchlets covered with the rudiments of flowers. Flowers ſeſſile with a ſpreading membranous border.—Native of the Cape of Good Hope.

21. Stems ſhrubby, aſcending, white. Leaves alternate, even; the lower ones of the branches commonly in pairs and equal, or two from each point. Spike terminating. Calyxes ſcarioſe, roſe-coloured, with a ſcarioſe, five-valved blunt little crown.—Native of Siberia[a].

22. Stem about two feet high or more, woody, erect, round, very much branched; the branches alſo erect, and thickly clothed with alternate, ſeſſile, ſemicylindrical, bluntiſh, fleſhy, even, almoſt upright, rather glaucous leaves. Flowers inconſpicuous, axillary, ſeſſile, ſolitary, green; with three ſmall, concave, ſcarioſe bractes[b]. Linneus remarks, that the germ is cylindrical, and the ſtyles three in number.

The leaves have an herbaceous flavour, with a ſlight degree of ſalt and ſome acrimony. It forms an elegant evergreen ſhrub, flowering in july and auguſt, not unworthy of a place in gardens[c].

Native of France, Spain, Barbary and Perſia, on the ſea-coaſt.—The firſt perſon mentioned as the diſcoverer of this plant in England is the famous Sir Thomas Brown, M.D. of Norwich, ſo well known by his *Religio Medici* and other learned productions. He found it on the Norfolk coaſt, where it ſtill grows, about Wells and Cley, as well as in Suffolk. Mr. Lambert found it at Weymouth[d]; and Dr. Pulteney plentifully on the iſthmus of Portland called Cheſil Bank; a large quantity oppoſite Fleet Houſe; abundantly at Windmill Point, Poole, and elſewhere on the coaſt of Dorſetſhire. Ray collected it abundantly on the Iſthmus of Portland, and mentions that Sir Thomas Brown had before that ſhown it him from the coaſt of Norfolk. Lobel ſays that he had gathered it plentifully on the Holms in the Briſtol Channel. Mr. Woodward obſerved it near Southwold in Suffolk.

23. This is a ſmall ſhrub, ſcarcely more than a foot high. Leaves nearly as in the preceding, but twice as long; the floral leaves are very ſhort, oblong and blunt. Flowers three ſeſſile on the axils of the leaves, on the branches of the former year, not towards the top. In other reſpects it has the habit of the preceding ſpecies.—Native of the Eaſt Indies.

24. This is diſtinct from the next ſpecies, in its round ciliate leaves, with long hairs.—Native of Siberia, in the ſalts by the Samara and the middle Jaik[e].

[d] Idem. [e] Willdenow.

25. Stem

Digitized by Google

25. Stem upright, hairy, aſh-coloured. Leaves linear, ſomewhat fleſhy, ſoft, aſh-coloured. Calyxes in pairs, heaped. Seed ſmall, within a three-toothed bag [f].

Stem ſuffruticoſe, flowering from bottom to top. Branches ſlender, panicled. Leaves alternate, villoſe, awnleſs. Flowers ſmall, one, two or three together, axillary, ſeſſile. Calyx tomentoſe, when the fruit is ripe ſpreading into a ſtar, each of the five parts terminated by a rigid awn, which is frequently hooked at the end [g].

Native of Egypt, and Barbary near Caſſa. Introduced in 1773, by John Earl of Bute. Annual: flowering in july and auguſt [h].

26. Stem two feet long, diffuſed, rough. Leaves blunt, quite entire, thick, ſmooth, oppoſite. Flowers axillary, glomerate, ſubſeſſile. Calycine ſegments emarginate, cowled at the top. Stigmas two, ſeſſile, oblong, erect. Capſule two-celled, with one rough black ſeed in each cell.—Native of the iſland of Mozambique in Africa [i].

27. This is a ſhrub, a foot in height, very much and cloſely branched. Branches upright, flexuoſe, ſmooth, yellowiſh: ſpines ſtout, axillary, ſolitary, an inch long, divaricate, ſimple or branched, floriferous. Leaves alternate, ſtiffiſh, glaucous, ſmooth, with an edge membranous on both ſides at the baſe, preſſed cloſe to the ſpines underneath, in the adult plant few. Flowers ſeſſile, ſolitary or glomerate, ſome from the ſpines themſelves, others from their axil: leaflets ternate, awl-ſhaped, with a membranous edge, ſurrounding each flower, the lower one a little larger than the two others.—Native of the higher mountains of Libanus [k].

28. Stems upright, very much branched: branches panicled, ſpiny; ſpines like needles. Bark in the younger plants white, in the older brown. Leaves alternate, ſmooth.—Native of Barbary near Tlemſen, in fallow fields.

29. Branches numerous, pubeſcent. Leaves alternate, villoſe, blunt; branch-leaves very much cluſtered, of the ſize and ſhape of *Sedum Acre*. Flowers axillary, ſeſſile, ſolitary, numerous. Calyx permanent, in the ripe fruit membranaceous.—Near Caſſa in Barbary, in ſands; alſo in Sicily.

30. Upright, very much branched. Leaves very ſoft ſmooth and juicy, very like thoſe of *Sedum album*, but a little ſhorter and thinner.—With the preceding.

31. Very much branched. Branches oppoſite, upright, knotty, ſmooth. Leaves ſmooth, fleſhy, awnleſs, depreſſed above. Flowers axillary, ſolitary, two or three together, ſeſſile. Bractes three, awl-ſhaped, ſmall; the lower larger. Calyx ſmall: ſegments blunt, upright. Membranes five, roſe-coloured, wide, like fans, rounded at the top, unequal, converging into a ſpreading bell, emerging below the tip of each ſegment of the calyx as the fruit ripens. Anthers four-cornered. Styles two.

This is a very handſome ſpecies, and quite diſtinct from its congeners.—Native of Tunis in Africa [l]; alſo of Spain and Sicily.

PROPAGATION AND CULTURE.

All the annual ſorts may be propagated by ſeed.

In thoſe countries where the preparation of Soda forms a conſiderable branch of commerce, the ſeeds are regularly ſown in a proper ſituation near the ſea; where they uſually ſhoot above ground in the courſe of a fortnight [m]. In Spain they plough the land four or five times, dung it well, and then, having turned the earth twice more, they make it ſmooth with boards inſtead of harrows, and ſow the ſeed in january and february, waiting always for wet weather. When the plant is about the bigneſs of a ſhilling, they clear off all the weeds [n]. About the time that the ſeeds become ripe, the plants are pulled up by the roots, and expoſed in a ſuitable place to dry, and there the ſeeds are collected: this being done, the plants are tied up in bundles, and burned in an oven conſtructed for that purpoſe; the aſhes, whilſt hot, being continually ſtirred with long poles. The ſaline matter, on becoming cold, forms a hard ſolid maſs, which is afterwards broken in pieces of a convenient ſize for exportation [o].

The ſhrubby ſorts may be propagated by layers or cuttings; but Salſola fruticoſa, it ſeems, can ſcarcely, if at all, be increaſed by the latter mode [p].

DESCRIPTIONS, &c.

1. Trunk generally crooked, eight or ten feet high to the branches, and one foot in diameter: bark very ſcabrous and deeply cracked. Branches exceedingly numerous, ſpreading, with their extremities perfectly pendulous, like the weeping Willow. Leaves oppoſite, petioled, oval or oblong, entire, very ſmooth and ſhining on both ſides, without veins, from one to two inches long, and about an inch broad. Stipules none. Panicle terminating, and from the exterior axils, compound. Flowers minute, very numerous, greeniſh yellow. Bractes minute. Calyx inferior, four-toothed, permanent. Corolla one-petalled; tube ſhort; border four-cleft: ſegments oblong, revolute. Filaments inſerted below the diviſions of the corolla, and rather ſhorter than them. Anthers oval. Germ globular. Style none. Stigma ſcabrous. Berry very minute, much ſmaller than a grain of black Pepper, ſmooth, red and juicy. Seed browniſh green.

This is a middle-ſized tree, a native of moſt parts of the Circars, though by no means common: it ſeems to grow equally well in every ſoil; and flowers and bears ripe fruit all the year round.

The berries have a ſtrong aromatic ſmell, and taſte much like garden creſſes.

The bark of the root is remarkably acrid; bruiſed and applied to the ſkin it ſoon raiſes bliſters, for which purpoſe the natives often uſe it: as a ſtimulant it promiſes to be a medicine poſſeſſed of very conſiderable powers [q]. Koenig ſent it from Tranquebar. Native alſo of the Perſian gulph.

2. This alſo is a middle-ſized tree, very much branched. Leaves alternate, very rough, unequally ſerrate, ſubpetioled. Flowers from the axils in heads containing eight of them or thereabouts, on a long

common

common peduncle, and very ſhort partial ones. Calyx four or five-parted, inferior, permanent. Corolla none. Filaments awl-ſhaped, reflex, double the length of the calyx. Stigma bifid, in ſome double. Berry yellow, roundiſh, ſmall, twin at the top.

3. Ten feet high, with many twiſted ſpreading branches. Leaves ſubſerrate, rough, alternate. Flowers axillary, on long peduncles. Calyx four-parted. Corolla none. Style bifid, with ſimple ſtigmas. Berry yellow, two-lobed, one-ſeeded, eſculent. Seed roundiſh, not arilled.

Both ſpecies are natives of Cochinchina, in woods and hedges; and are not eaſily diſtinguiſhed unleſs when they are in flower*.]

SALVIA. (*From* ſalvere; *on account of its healing qualities.*)

Lin. gen. n. 39. *Reich. n.* 42. *Schreb. n.* 50. *Tournef. t.* 83. *Juſſ.* 111. *Gærtn. t.* 66. Horminum. *Tournef. t.* 82. Sclarea. *Tournef. t.* 82.

Claſſ. 2. 1. Diandria Monogynia.

Nat order of *Verticillatæ*. *Labiatæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, tubular, ſtriated, gradually widening and compreſſed at the top: *mouth* erect, two-lipped; lower lip two-toothed.

COR. one-petalled, unequal: *tube* widening at the top, compreſſed; *border* ringent, *upper lip* concave, compreſſed, curved inwards, emarginate, *lower lip* wide, trifid, *middle ſegment* larger, roundiſh, emarginate.

STAM. *Filaments* two, very ſhort; two threads are faſtened tranſverſely to theſe almoſt in the middle, on the lower extremity of which is a *gland*, on the upper an *Anther*.

PIST. *Germ* four-cleft. *Style* filiform, very long, in the ſame ſituation with the ſtamens. *Stigma* bifid.

PER. none. *Calyx* very ſlightly converging, having the ſeeds in the bottom of it.

SEEDS four, roundiſh.

OBS. *The ſingular forking of the filaments conſtitutes the eſſential character.*

Rudiments of two ſtamens, but barren ones, in the opening of the corolla. Gland in moſt ſpecies callous, but in a few a ſort of rudiment of an anther with little or no pollen occurs. (The gland is one cell of the anther, commonly ſteril, connected with the other cell fertile, having an antheraceous membrane lengthened out into a thread.)

Salvia Tournef. *has the upper lip ſickle-ſhaped or vaulted; the lower flat or bent back on the ſides.*

Horminum Tournef. *has the upper lip aſcending, ſhort; the lower with the middle ſegment concave.*

Sclarea Tournef. *has the upper lip erect, ſickle-ſhaped; the lower lip with the middle ſegment concave.*

ESSENTIAL CHARACTER.

Cor. unequal. *Filam.* faſtened tranſverſely to a pedicel.

H. verbenacæ laciniis anguſtifolium. *Triumf. obſ.* 66. *t.* 66.
H. ſilv. quarti quinta ſpecies. *Cluſ. hiſt.* 2. 31. *f.* 1.

Leaves ferrate ſinuate ſmoothiſh, corollas narrower than the calyx.

[29. Salvia ſcabra. *Rugged Sage.*
Lin. ſyſt. 72. *Willd.* 1. 137. *ſuppl.* 89.

Rugged, leaves lyrate toothed wrinkled, ſtem panicle-branched.

30. Salvia runcinata. *Runcinate-leaved Sage.*
Lin. ſyſt. 72. *Willd.* 1. 138. *ſuppl.* 89.

Rugged, leaves runcinate-pinnatifid toothed, flowers ſpiked whorled.]

31. Salvia clandeſtina. *Cut-leaved Sage.*
Lin. ſpec. 36. *ſyſt.* 70. *Reich.* 1. 66. *Willd.* 1. 138. *Etling. ſalv. n.* 20. *Zinn. goett.* 198. *Desfont. atlant.* 23.
Horminum lyratum. *Mill. dict. n.* 2.
H. ſylveſtre, inciſo folio, cæſio flore, italicum. *Barr. rar.* 24. *t.* 220.

Leaves ſerrate pinnatifid very much wrinkled, ſpike obtuſe, corollas narrower than the calyx.

[32. Salvia auſtriaca. *Auſtrian Sage.*
Lin. ſyſt. 69. *Willd.* 1. 138. *Ait. kew.* 1. 41. *Etling. ſalv. n.* 41. *Crantz, auſtr.* 4. 238. *Jacqu. auſtr.* 2. 8. *t.* 112.

Leaves ovate and cordate eroſe-ſinuate, root-leaves petioled, ſtem almoſt leafleſs, ſtamens double the length of the corolla.

33. Salvia pyrenaica. *Pyrenean Sage.*
Lin. ſpec. 36. *Reich.* 1. 67. *Willd.* 1. 138. *Etling. ſalv. n.* 42.
Horminum pyrenaicum glutinoſum anguriæ folio. *Herm. par.* 187. *t.* 187.
Sclarea pyrenaica glutinoſa, foliis ſinuatis. *Tournef. inſt.* 179.

Leaves obtuſe eroſe, ſtamens double the length of the corolla.

34. Salvia diſcermas. *Long-ſpiked Sage.*
Lin. ſpec. 36. *ſyſt.* 70. *Reich.* 1. 67. *Willd.* 1. 139. *mant.* 318. *Etling. ſalv. n.* 32. *Arduin. ſpec.* 1. 9. *t.* 1. *Allion. hort.* 49. *n.* 4. *Retz. obſ.* 3. 7. *n.* 4.
Horminum ſylveſtre majus flore albo, integris foliis. *Barr. ic.* 187.

Leaves cordate-oblong eroſe, ſtamens equal to the corolla.

35. Salvia rugoſa. *Wrinkled-leaved Sage.*
Lin. ſpec. ed. Willd. 1. 139. *Ait. kew.* 1. 42.

Leaves cordate oblong-lanceolate eroſe-crenate wrinkled ſomewhat hairy, ſtamens ſhorter than the corolla.

36. Salvia nubia. *Nubian Sage.*
Lin. ſyſt. 70. *Willd.* 1. 139. *Murr. comm. gott.* 1778. *p.* 90. *t.* 3. *Ait. kew.* 1. 42.

Leaves oblong ſubcordate unequilateral wrinkled crenate ſometimes eared at the baſe.

37. Salvia nilotica. *Nile Sage.*
Lin. ſyſt. 70. *Willd.* 1. 140. *Murr. comm. gott.* 1778. *p.* 88. *t.* 2. *Jacqu. hort.* 3. *t.* 92. *Retz. obſ.* 3. 7. *n.* 3.

Leaves ſinuate angular crenate-toothed, teeth of the calyxes ſpiny, angles and margin of the aperture ciliate.]

38. Salvia mexicana. *Mexican Sage.*
Lin. ſpec. 37. *Reich.* 1. 67. *Willd.* 1. 140. *hort. cliff.* 13. *Etling. ſalv. n.* 35. *Cavan. ic.* 1. 16. *n.* 24. *t.* 26.
Sclarea mexicana. *Mill. dict. n.* 14.—altiſſima, facie heliotropii. *Dill. elth.* 339. *t.* 254. *f.* 330.

Leaves ovate, acuminate at both ends, ſerrate.

[39. Salvia amethyſtina. *Amethyſtine Sage.*
Smith ic. ined. 2. 27. *t.* 27. *Willd. ſpec.* 1. 140.

Leaves cordate acute ſerrate woolly beneath, whorls naked, calyxes trifid, corollas pubeſcent.

40. Salvia fulgens. *Fulgid Sage.*
Lin. ſpec. ed. Willd. 1. 140. *Cavan. ic.* 1. 15. *n.* 21. *t.* 23.

Leaves cordate acute crenate wrinkled tomentoſe beneath, whorls naked, calyxes trifid, helmet of the corollas villoſe.

41. Salvia formoſa. *Shining-leaved Sage.*
Lin. ſpec. ed. Willd. 1. 140. *L'Herit. ſtirp.* 1. 41. *t.* 21. *Ait. kew.* 1. 43. *Curt. magaz.* 376.
S. Leonuroides. *Gloxin obſ. bot.* 15. *t.* 2.

Leaves ſubcordate, helmet of the corollas bearded, calyxes three-lobed, ſtem ſruteſcent.

42. Salvia tubiflora. *Long-tubed Sage.*
Smith ic. ined. 2. 26. *t.* 26. *Willd. ſpec.* 1. 141.

Leaves cordate crenate ſomewhat hairy, calyxes trifid, corollas very long tubular, ſtamens ſtanding out.

43. Salvia longiflora. *Long-flowered Sage.*
Lin. ſpec. ed. Willd. 1. 141.
S. tubiſera. *Cavan. ic.* 1. 16. *n.* 23. *t.* 25.

Leaves ovate acute ſerrate pubeſcent, calyxes trifid, corollas very long tubular pubeſcent, ſtamens the length of the corolla.

44. Salvia coccinea. *Scarlet-flowered Sage.*
Lin. ſyſt. 71. *Willd.* 1. 141. *ſuppl.* 88. *Murr. comm. gott.* 1778. *p.* 86. *t.* 1. *Etling. ſalv. n.* 11. *Ait. kew.* 1. 43.

Leaves cordate acute tomentoſe ſerrate, corollas narrower than the calyx and twice as long.

45. Salvia pſeudococcinea.
Lin. ſpec. ed. Willd. 1. 141. *Jacqu. collect.* 2. 302. *ic. rar.* 2. *t.* 209.

Leaves ovate acute ſerrate unequal at the baſe, ſtem hairy, corollas double the length of the calyx.

46. Salvia hiſpanica. *Spaniſh Sage.*
Lin. ſpec. 37. *Reich.* 1. 67. *Willd.* 1. 141. *Gærtn. fruct.* 1. 316. *Etling. ſalv. n.* 18. *Scop. carn. n.* 35. *Allion. pedem. n.* 58. *Kniph. orig. t.* 2. *n.* 78. *Sabb. hort. rom.* 3. *t.* 22. *Ard. ſpec.* 10. *t.* 2.
Sclarea hiſpanica. *Tabern. hiſt.* 764. *ic.* 374.

Leaves ovate, petioles mucronate each way, ſpikes imbricate, calyxes trifid.

47. Salvia abyſſinica. *Abyſſinian Sage.*
Lin. ſpec. ed. Willd. 1. 142. *Jacqu. collect.* 1. 132. *ic. rar.* 1. *t.* 6. *Ait. kew.* 1. 43.

Lower leaves lyrate, upper cordate, flowers in whorls, calyxes mucronate ciliate.]

48. Salvia verticillata. *Whorl-flowered Sage.*
Lin. ſpec. 37. *ſyſt.* 70. *Reich.* 1. 68. *Willd.* 1. 142. *hort. cliff.* 495. *upſ.* 11. *Etling. ſalv. n.* 247. *Hoffm. germ.* 10. *Roth. germ.* 1. 12. 2. 32. *Scop. carn. n.* 34. *Crantz. auſtr.* 241. *Kniph. orig.* 6. *t.* 79. *Hall. helv. n.* 251. *Berg. phyt.* 2. 91.

DESCRIPTIONS, &c.

[This large genus conſiſts of herbs or underſhrubs. The flowers are from one to three together from a bracte or a leaf, frequently in ſpikes. The filaments are ſtipitate in the middle in the Salvia of Tournefort; but beyond the middle in the Sclarea of the ſame author. The upper lip of the corolla is compreſſed and ſickle-ſhaped in both theſe: but in Horminum of Tournefort it is concave and ſhaped like the bowl of a ſpoon. The ſtyle in S. cretica is double, which is unuſual in the natural order of Labiatæ, but its ſeeds are abortive[1]. Mr. Miller has followed Tournefort in dividing the genus, and has treated of it under the three articles of *Horminum*, *Salvia* and *Sclarea*.

Our Engliſh name *Sage* is from the French *Sauge*. In German it is *Salbey*, which is evidently from the Latin. Clary is plainly from *Sclarea*, which is from σκληρος, hard; the ſtalks being hard and not ſucculent. Horminum is ſaid to be απο του ορμαν, quòd ad venerem ſtimulet, according to Dioſcorides.

1. This is an annual plant, a foot high, ſtiff and brachiate. Leaves naked, rugged, very much wrinkled underneath. Spikes as it were ſpiny. Flowers in threes, pedicelled, very minute. Corollas white, with the upper lip very ſhort, emarginate, not compreſſed; the lower trifid, with the middle ſegment violet-coloured and dotted. Stamens ſmall with blueiſh anthers[1].

Gouan affirms that he has moſt commonly found four ſtamens in the flowers.

Vahl ſays that the wild plant is a low rigid little ſhrub, ſcarcely a ſpan in height, aſh-coloured and reverſely hairy; with the leaves turned back at the edge and hairy.

Desfontaines deſcribes it as of an aſh colour, upright, and very much branched: the branches ſlender, with ſhort reverſe hairs. The leaves wrinkled, waved, running down into the petiole. The whorls diſtinct; the lower having ſix, the upper two flowers, all pedicelled, and the upper ones abortive. Bractes very ſmall, ovate, acute, ſhorter than the pedicel. Calyx villoſe, ſtriated: with the upper lip ſhorter, two-toothed, and the mouth ciliate. Corolla white, ſmall, dotted; with the upper lip very ſhort.

Native of Egypt and the Canary iſlands. Cultivated in the ſands about Caſſa in Barbary. Introduced in 1770, by Monſ. Richard. It flowers in june and july[2].

2. Native of the Cape of Good Hope, where it was found by Maſſon, and introduced in 1774. It flowers in december and january. It is ſhrubby[3].

3. Calyxes two-leaved. Styles two, with ſimple ſtigmas[4]. In the opinion of Willdenow, it ſeems to be only a variety of S. officinalis.—Native of the iſland of Candia. Cultivated in 1760 by Mr. James Gordon. It flowers from june to auguſt, and is ſhrubby[5].

4. Root-leaves oblong, ſinuate and ſometimes jagged, reſembling thoſe of the common Bugle, but larger, above dark green with dark-purple ſpots about the veins, beneath duſky purple; which colour the ſtems frequently have alſo. The whole is hirſute and hairy; the hairs on the upper part ſpringing from dots or ſmall tubercles. The ſtem is a long ſpan or a foot high, ſingle or ſeveral, with one or two joints, at each of which is a pair of leaves, not branched; at the upper part are ſeveral whorls of flowers, ſix in each placed in a ring, with two leaves beneath; theſe in the upper whorls are ſmall, entire, like thoſe of Myrtle; in the lower whorl longer, with here and there a cut on the edge. Calyxes biggiſh, ſtreaked with five lines, two-parted, the upper ſegment wider and trifid, the lower narrower and bifid. Corollas pale blue; the upper lip bifid with widiſh wings ending in a ſhort cuſp, the lower alſo bifid, ſometimes notched about the

[1] Juſſieu. [2] Linn. ſyſt. [3] Hort. kew. [4] Idem. [5] Schreber. [6] Hort. kew.

edges.

Digitized by Google

edges. Seeds biggiſh, bluntly three-cornered, with the outer part protuberant, roundiſh; the inner where they touch each other pared off and angular; when ripe they are blackiſh [a].

Linnæus made two ſpecies of this in his *Species Plantarum*, under the names of *Salvia lyrata* and *Horminum virginicum*; but in his *Mantiſſa* he referred the latter to the former, it being the ſame plant, bearing clandeſtine flowers in Europe.

Native of Virginia and Carolina. Cultivated in 1728, by James Sherard, M.D.[b] The ſeeds, from Virginia, were given to him by Charles Du Bois, Eſq. treaſurer to the Eaſt India Company [c].

5. Stems branched, upright, five feet high. Leaves narrow, long, beneath tomentoſe, whitiſh, above dark green; petioles ſhort, ſubconnate, with very ſmall glands at the baſe reſembling brown dots. Flowers in very long interrupted ſpikes, compoſed of many-flowered whorls, covered with a lanuginous violet-coloured nap. Calyx alſo violet-coloured, with the upper lip entire and acute, the lower ſhortly bifid. Corolla white, twice as large as the calyx; upper lip arched, plaited, entire, villoſe; lower trifid, with the ſegments rounded, nearly equal, and under them a ſhort excreſcence.

Native of Mexico. It flowers in the royal garden at Madrid in november and december [d].

6. This is a handſome plant. Stem indiſtinctly quadrangular, pubeſcent. Leaves very narrow, ſmooth above, pubeſcent beneath. The whorls have each two bractes which are ovate, acuminate, and longer than the calyx; which is as in S. officinalis, only larger and green. Corolla as in that, but larger. There are commonly leafy branches from the upper axils of the leaves.—Native of Tauris [e].

7. The common garden or officinal Sage is a branching ſhrub, about two feet in height. The younger branches are tomentoſe and whitiſh. The leaves are wrinkled, cinereous white or tinged with duſky purple, on very ſhort petioles, ſometimes eared at the baſe. Flowers terminating, in long ſpikes compoſed of ſix-flowered whorls, approximating yet diſtinct. Bractes ovate, acute, deciduous. Calyx ſtriated, five-toothed; the teeth acute, the three upper ones nearly equal and ſmaller. Corolla blue: upper lip blunt, emarginate; lower three-lobed, the ſide lobes bent back, the middle lobe larger and two-lobed [f].

Native of the South of Europe, and Barbary. Cultivated in 1597 by Gerarde [g]: and doubtleſs we had it much earlier in our gardens.]

Mr. Miller enumerates the following varieties:—1. The common green Sage. 2. The Wormwood Sage. Salvia abſinthites. *Ger. emac.* 764. *n.* 7. *Raii hiſt.* 511. Johnſon ſpeaks of this as a rarity and a tender plant. He firſt ſaw it with Mr. Cannon. S. minor altera. *Baub. pin.* flore rubente. *Park. theat.* 50. *n.* 7. 3. 3. Green Sage with a variegated leaf. S. variegata vulgaris. *Ger. emac.* 764. 6. *Raii hiſt.* 510. 4. Red Sage. S. nigra. *Baub. pin. Raii hiſt.* 509. 2. 5. Red Sage with a variegated leaf. [Salvia variegata. *Park. parad.* 446.—elegans. *Ger. emac.* 764. 5. Painted or Party-coloured Sage: with red leaves ſtriped with white, or white red and green mixed. It was firſt found, ſays Johnſon, in a country garden by Mr. John Tradeſcant, and by him imparted to other lovers of plants.] There is alſo Spaniſh Sage. S. hiſpanica. *Mill. dict. n.* 4.—lavendulæ folio. *Tournef. inſt.* 181. The leaves linear-lanceolate, very narrow and quite entire, in cluſters on the ſide of the ſtalks; they are very hoary, and the branches are covered with a hoary down: the leaves on the upper part of the ſtalk are narrower than thoſe of Roſemary. The flowers grow in cloſer ſpikes, and are of a light blue colour.

The variety with red or blackiſh leaves is the moſt common in the Engliſh gardens; and the Wormwood Sage is in greater plenty here than the common green-leaved Sage.

[Sage has a ſtrong fragrant ſmell, and a warm bitteriſh aromatic taſte. In ancient times it was much celebrated as a remedy of great efficacy, but at preſent few practitioners conſider it as of much importance; and although frequently employed as a ſudorific, it ſeems to have no advantage over many other plants; and by ſome it has been ſucceſsfully uſed even for the purpoſe of reſtraining inordinate ſweating. Van Swieten found it to be remarkably efficacious in ſtopping night ſweats, infuſed in wine or ſpirit; but Quarin remarks, that a ſtrong infuſion in water has been experienced to be equally ſucceſsful. Van Swieten alſo found it uſeful in reſtraining the improper continuance of a flow of milk from the breaſts of women after they had weaned their children. As poſſeſſing a ſhare of aromatic and aſtringent power, it may prove a ſerviceable tonic in a debility of the ſtomach and nervous ſyſtem. The Chineſe value it highly for this purpoſe, and prefer it to their own tea. The power of this plant, in reſiſting the putrefaction of animal ſubſtances, has alſo been adduced in proof of its medicinal efficacy. From the experiments of Etlinger, it has a conſiderable ſhare of antiſeptic power [h].

Sage appears in the catalogue of the Materia Medica of the London College, but is not directed to be uſed in any of the preparations. It ſtill keeps its ground in fomentations among the common people, and in the kitchen for ſauce to luſcious and ſtrong meats.]

8. This is generally called Balſamic Sage by the gardeners. The ſtalks do not grow ſo upright as thoſe of the common Sage; they are very hairy, and divide into ſeveral branches. Leaves broad, woolly, on long petioles, ſerrate, and rough on the upper ſurface: the leaves on the flower-ſtalks are oblong-ovate, on ſhorter petioles, and very ſlightly ſerrate. The whorls are pretty far diſtant, and few flowers in each; they are of a pale blue, and about the ſame ſize with thoſe of the common ſort. It flowers in june, and in good ſeaſons the ſeeds ripen in autumn. This Sage is preferred to all the others for making tea.

9. The leaves of this, which is the common Sage of Virtue, are narrower than thoſe of the common ſort; they are hoary, and ſome of them are indented on their edges towards the baſe, which indentures have the appearance of ears. The ſpikes of flowers are longer than thoſe of the two preceding ſorts, and the whorls are generally naked. The flowers are ſmaller, and of a deeper blue than thoſe of the common Sage.

[Native of the South of Europe, (Crete and Syria.) Cultivated in 1597, by Gerarde [i].

It has the habit of S. officinalis, and is all over hoary with a nap. It is ſingular in having earlets at the baſe of the leaves [k].—This however is not conſtant; ſometimes there is only one earlet, and ſometimes none. The leaves under the whorls are of a different ſhape from the others. The flowers are for the moſt part three together. Calyx five-cleft; with three ſegments placed by the upper lip of the corolla, and two by the lower lip. Helmet or upper lip of the corolla arched and bifid: beard or lower lip four-cleft.]

10. Stem ſhrubby, four or five feet high, dividing into ſeveral branches. Flowers of a pale blue colour. The branches have often punctures made in them by inſects, producing protuberances as big as Apples, in the ſame manner as galls upon the Oak, and the rough balls on the Briar. [The common Sage has the ſame excreſcencies in the iſland of Candia or Crete, and they carry them to market there under the name of Sage Apples.

Tournefort thus deſcribes this ſpecies, which ſeems to have been confounded with the preceding. It is a very tufted ſhrub, two or three feet high. Trunk twiſted, hard, brittle, two inches thick, ruſſet, covered with a gray chopped bark, and divided into ſeveral branches the ſize of the little finger, ſubdivided into others, the ſhoots from which are ſquare, oppoſite, whitiſh, cottony. Leaves two inches and a half long or more, an inch or fifteen lines wide, rough like ſhagreen, whitiſh, curled, elegantly veined, ſtiff and hard, dotted beneath, on a petiole ſeven or eight lines in length, cottony and grooved. Spike of flowers a foot

Digitized by Google

long, compoſed of cloſe whorls. Each flower is an inch or fifteen lines in length. Calyx half an inch long, pale green tinged with purple, cut irregularly into five points. Upper lip of the corolla hollowed like the bowl of a ſpoon, villoſe, of a deeper or paler blue, eight or ten lines in length: lower lip a little longer, trifid; the two lateral ſegments bordering the opening between the two lips, the middle one rounded, emarginate, pale blue, curled and marbled, ſtriped with white about the middle. Seeds oval, blackiſh, a line in length. The odour partakes of that of common Sage and Lavender.

Found by Tournefort in Candia. Cultivated in 1699, by the Hon. Charles Howard [k].

11. Stem high, upright, ſmooth. Leaves like thoſe of Nettle, or rather of Scrophularia, having a wide baſe, but going off gradually at the top into a ſharp point. Petiole an inch long. Flowers in whorls, ſix together, ſmall [l]. Upper lip ſhort. Piſtil longer than the upper lip [m].—Native of Virginia and Florida.

12. Root fibrous annual. Stem aſcending, branched, a foot high, diffuſed, knotty, even. Leaves ſhortly acuminate, hiſpid above, ſmooth beneath. Petioles four-cornered, red, pubeſcent. Bractes oppoſite, alternate, awned; within them two or three ſmall blue flowers. Calyx angular-ſtriated, covered with glandular hairs. Style the length of the upper lip. Seeds two, one of which only ripens; and that is ovate, compreſſed and black. It differs from the other ſpecies in its looſe ſpikes and remote flowers.

Native of the Weſt Indies [n]. In Jamaica this little plant is found creeping under every hedge and buſh in the lower lands: it runs frequently to the length of two or three feet, but always roots at the lower joints. It has a faint ſmell of Balm when firſt pulled [o].

13. Stem herbaceous, upright, ſtiff, ſomewhat villoſe, with the angles blunt. Leaves netted-veined, wrinkled eſpecially beneath, two inches or more in length, ſcarcely pubeſcent, bluntly ſerrate; ſerratures equal. Petiole the ſame length with the leaf. Pedicels in whorls, about eight. Bractes awl-ſhaped, deciduous. Calyx bell-ſhaped, with eight raiſed hairy lines, bifid: ſegments ovate, acuminate; lower bifid, upper undivided. Corolla a little longer than the calyx, blue.—It differs from *S. ſerotina* in having the ſtem leſs hairy; the leaves not ſoftly villoſe, but wider, acute, with equal ſerratures; and the lines on the calyx hairy only, not glutinous [p].

Sent to Vahl by Bellardi, but from what country unknown. The plant figured and deſcribed by Cavanilles, under the name of *S. polyſtachya*, appears to Willdenow ſcarcely to differ from this, although the leaves be ovate, the ſpikes ſhorter and the flowers larger. If that ſhould prove to be the caſe, it is a native of Mexico. Cavanilles ſaw it flowering in november and december in the royal garden at Madrid.

He deſcribes his *polyſtachya* as a fathom high, with the angles of the ſtem acute; the branches tender and ſomewhat villoſe. Leaves longer than the petioles, ovate-acute, ſerrate, ſoft, glaucous beneath: the baſe of the petioles externally biglandular. Flowers in many denſe terminating ſpikes; the whorls compoſing them approximating and many-flowered. Calyx ſhort, villoſe, ſtriated. Corolla ſmall, blue: upper lip ſhort, arched, entire; lower trifid, with the middle ſegment larger and emarginate.

He remarks, that this, together with the four other ſpecies which he deſcribes, (fulgens, leucantha, tubifera and mexicana) have the upper lip almoſt entire; and the calyx in all two-lipped; the upper lip entire, one-toothed; which Juſſieu makes three-toothed.

14. Root biennial. Stem ſuffruticoſe, a foot and half high, brachiate, ſcarcely tomentoſe; with the lower branches cauleſcent. Leaves waved and very finely ſerrate, ſcarcely tomentoſe, but very ſoft and paler underneath. Spike ſcarcely peduncled, whorled. Calyx cylindrical, narrow, ſtriated, with a trifid mouth; the lower ſegment wider. Corolla minute, the ſize of Ziziphora, ſcarcely larger than the mouth of the calyx. Odour of Nepeta, unpleaſant, ſtrong. Calyxes peduncled, with bractes ſo ſmall as to be hardly viſible.—Suppoſed to be a native of the iſland of Chios [q].

15. This is an herbaceous annual plant, with long, capillary, creeping roots. Stem decumbent, four or five inches long, the lower part creeping, ſubdivided, aſcending, ſtriated, pubeſcent. Leaves ſmall, petioled, remote, tooth-ſerrate, nerved, pubeſcent. Spikes terminating, upright, compoſed of approximating, three or four-flowered whorls. Flowers pedicelled, ſmall, blue. Bractes ovate, very ſmall, two, three or four under the peduncles. Calyx gibbous underneath, three-toothed: upper ſegment ſhorter retuſe, very minutely three-toothed; the two anterior ones a little longer, blunt; all hirſute with glandular hairs; glands pellucid, azure. Lower lip of the corolla white in the middle, blue at the edge; the opening with blue lines. Seeds two naked, erect, ovate, compreſſed, black. It is eaſily known by its habit and ſmallneſs: and flowers all the year.

Native of Jamaica, in the gravelly and graſſy parts of the higheſt mountains.

16. This is an annual plant, and has altogether the appearance of S. Horminum. Stem upright or decumbent at the baſe, branched, hirſute with longiſh villoſe hairs. Leaves cordate and ovate, blunt, wrinkled, pubeſcent, equally and ſlightly crenate; the lower ones on long hirſute petioles. Whorls ſix-flowered; the lower ones diſtinct and often remote; the upper ones confluent. Bractes large, cordate, acute, hirſute; the lower ones crenate, longer than the calyx; there are commonly four interior ones beſides, which are linear-ſubulate and ciliate. It has the flowers of S. Horminum, on ſhort pedicels. Calyx villoſe, elongated, deeply ſtriated, four-toothed, the teeth acute and ſhort: when the fructification is complete, it nods. The upper lip is emarginate. Corolla ſmall, roſe-coloured, one third part longer than the calyx: upper lip ſemiorbicular, bluntiſh; lower three-lobed, the middle lobe concave, emarginate, of a paler colour. Style ſhorter than the corolla. Seeds four, brown, ſomewhat compreſſed.—Give it a coloured coma, and it will be S. Horminum. Perhaps it may be no more than a variety.—The ſpecies here deſcribed is certainly the ſame with that of Tournefort's corollary. In S. viridis of Linneus and Jacquin the upper lip of the corolla is blue, whereas in the African it is roſe-coloured: in other reſpects they are alike [r].

Jacquin deſcribes it as about a foot high, branched little or not at all. Calyx nearly cylindrical green, hirſute with clammy capitate hairs. Upper lip of the corolla oblong, a little hirſute on the outſide, violet-coloured, converging: lower lip blue, blunt, the lateral ſegments oblong, the middle one concave and roundiſh. Stigma violet-coloured. Seeds ovate, compreſſed a little, black. The plant has a ſtrong ſmell.

Native of Italy, and Africa on the hills about Tunis. Introduced in 1776, by Monſ. Thouin [s].]

17. Stems erect, about a foot and half high. Leaves ſhaped like thoſe of the common red Sage, gradually diminiſhing in ſize to the top. The ſtems have whorls of ſmall flowers, and are terminated by cluſters of ſmall leaves, (or barren bractes, called the *coma* by Linneus) and forming two varieties; one with purple, and another with red tops. For the ſake of this coma they are preſerved in gardens for ornament. They flower in june and july, and their ſeeds ripen in the autumn.

[Native of the South of Europe. Cultivated in 1597 by Gerarde [t].

18. Radical leaves oblong, obtuſe, cordate at the baſe, footſtalked, contracted and wrinkled, with very numerous veins, undulated or ſinuated at the margins, of a dark green and ſmooth above, except on the midrib and veins: they are about ſix or nine inches long, and two or three broad: the cauline leaves are foot-ſtalked, but thoſe on the upper part are ſeſſile, and are crenated, wrinkled, and but ſlightly hairy. Stems hirſute, obtuſely quadrangular, upright, about

[k] Moriſon. [l] Idem. [m] Linn. ſyſt. [n] Swartz, [o] Browne. [p] Vahl. [q] Linn. mant. [r] Desfontaines. [s] Idem. [t] Hort. kew.

Digitized by Google

four feet tall, and have ſeveral long branches growing at acute angles from their ſides, and terminated by the long flowering ſpikes. Bractes entire, cordate, and acute, from each of which proceed three flowers on ſhort footſtalks. Calyx rough and bilabiate: corollas white or pale roſe-colour, or ſometimes blueiſh [x].

Native of the Pyrenean mountains. Cultivated in 1758, by Mr. Miller. It flowers from july to november [x].]

19. This has an abiding root, from which come out many cordate-lanceolate leaves, about four inches long, and an inch and half broad, of a bright green colour, with many white ſpots diſperſed on their ſurface. The ſtalks are thick, and riſe near three feet high, having ſeſſile leaves in pairs below, and above long looſe ſpikes of flowers in ſmall whorls, with coloured bractes. [Theſe bractes are ovate and three-flowered. The upper lip is compreſſed, and has ſeſſile glands ſcattered over it below the tip. The leaves are oblong and ſubcordate at the baſe, villoſe beneath. Opening of the corolla cloſed with ſcales, which terminate one tip of the filament. Fulcre ſhorter than theſe ſcales. Stamen below the contact of the fulcre toothed [y].

Native of Auſtria, Bohemia, Sileſia, the hills about Turin, &c.—Cultivated in 1759, by Mr. Miller. It flowers from june to october [z].

Etlinger unites this with the next; but they are very diſtinct [a].]

20. This alſo has an abiding root, ſending out many ſmooth leaves, about the ſize and ſhape of broad-leaved Sage. Stalks ſlender, a foot and half high, with ſmaller leaves towards the bottom, and ſpikes compoſed of ſmall whorls of blue flowers in the upper part.

[Root-leaves cordate; ſtem-leaves ovate-lanceolate, equally ſerrate, naked above, ſubtomentoſe beneath. Spikes before the flowers open exactly ſquare, with coloured bractes ſhorter than the flower. The corollas have impalpable dots ſcattered over them: the middle lobe of the lower lip is cloſely bent back beneath the calyx [b].

Reichard remarks, that Crantz unites this with the preceding ſpecies.

Native of Auſtria and Tartary. Cultivated in 1728, by Mr. Miller. It flowers from june to october [c].]

21. This alſo is an abiding plant, with the roots running deep in the ground. Lower leaves about four inches long, and an inch and half broad in the middle. Stalks ſlender, ſtiff, a foot and half high, with ſmaller leaves of the ſame ſhape in pairs. Flowers in ſmall whorls, diſpoſed in looſe ſpikes at the top of the ſtalks; they are ſmall and blue.

[It has the ſtature of S. pratenſis. Angles of the ſtem blunt. Leaves very much wrinkled, ſomewhat downy underneath, bluntly crenate. Panicle brachiate, rod-like. Bractes ſhorter than the calyx; which is five-cleft; the ſegments equal and acuminate. Corollas white. Style double the length of the upper lip [d].

Stem hairy. Root-leaves elliptic: ſtem-leaves ovate; the lower ones petioled, the upper ſeſſile. Bractes ſeſſile, leſs wrinkled than the leaves, toothed, acuminate, about the length of the calyxes. Flowers ſix in a whorl, white, like thoſe of S. pratenſis, but larger. Calyx five-toothed, awned, compreſſed. Filaments white, the length of the upper lip. Style longer, purple. It laſts two or three years, and has a ſweet ſmell [e].

Native of Syria: found in Paleſtine by Haſſelquiſt. Cultivated in 1759, by Mr. Miller. It flowers in july [f].

22. Root perennial. Lower part of the ſtem woody. Reſt of the ſtem herbaceous, upright, a foot and half high, little branched. The whole plant has a ſtrong ſweet ſmell, and has clammy hairs tipped with capitate glands. Leaves cordate at the baſe, petioled, indiſtinctly crenulate, ſharpiſh, veined, wrinkled. Whorls diſtant, ſix-flowered; the flowers on ſhort pedunicles, ſupported by a roundiſh-cordate acuminate ſhorter bracte. Each lip of the calyx acuminate and two-toothed; the lower more deeply cut. Corolla purple; the lower lip paler, with the lateral ſegments oblong; the upper villoſe-viſcid on the outſide [g].

Native of Italy. Introduced in 1773, by John Earl of Bute. It flowers in may and june [h].]

23. This has large ſwelling roots, like thoſe of Peony. Root-leaves five or ſix inches long, and almoſt four broad at their baſe, where they are eared; they are on pretty long foot-ſtalks. Between theſe ariſe ſtrong ſtalks about four feet high, having on the upper part looſe ſpikes of whorled flowers of a purple colour.

[Stem upright, viſcid. Leaves repand, ſmooth above, with ferruginous ſpots; the uppermoſt ſmall and ſeſſile. Upper lip of the calyx concave above, keeled, blunt, emarginate; lower bifid. Corolla blue, like that of S. ſylveſtris: the upper lip ſickle-ſhaped; the lower trifid; the middle ſegment very wide, emarginate, bagged, reflex. Style longer than the upper lip. Anthers coadunate, black, with a yellow pollen [i].

The whole plant is hiſpid. Petiole ſhorter than the diameter of the leaf. From twenty to twenty-four flowers in a whorl, with dry bractes. Peduncles unequal. Calyx five-cleft, ſublabiate. Opening of the corolla cloſed by two plates: upper lip ovate, contracted behind, villoſe; lower trifid, with the lateral ſegments ſubovate, the middle one concave and obtuſe; tube ferruginous, gibbous below. Filaments ferruginous: anthers blue. Style long, ferruginous [k].

Native of Italy and Iſtria. Cultivated by Mr. Miller in 1759.

24. Root perennial. Leaves oblong, nearly ſmooth, irregularly crenate, wrinkled and veiny; the root-leaves and lower ſtem-leaves on longiſh footſtalks; and ſometimes ſinuate; the uppermoſt ſeſſile, embracing the ſtem, ſharply pointed. Long whorled ſpikes of large blue flowers, ſix in a whorl, terminate the ſtem and branches, with a pair of very ſmall heart-ſhaped acuminate bractes to each whorl, whence Linnæus characterizes it *verticillis ſubundis*, the bractes being ſo much leſs conſpicuous than in moſt other ſpecies. The flower-ſtalks and calyx, as well as the apex of the corolla, are hairy and viſcid [l].

Dr. Withering remarks that the floral leaves are about the length of the calyx, which is ſpread open; that the corolla, of a blueiſh purple, is four times as large as the calyx, with the helmet hooked like the handle of a walking-ſtick; and that its gumminеſs, not being conſtant, ought not to make a part of the ſpecific character.

Native of many parts of Europe, in dry paſtures and by hedge ſides. It is one of the moſt ſpecious, as well as one of the more rare plants of Britiſh growth. The indefatigable Ray never found it wild in England. It ſeems to have been firſt noticed by Bobart, as having been found by Watts near Cobham in Eſſex; but that ſhould have been Kent, where Lord Darnley has a ſeat, and where Mr. Jacob Rayer has ſince gathered it. Mr. Swayne found it at Wick-clifts in Glouceſterſhire: Dr. Sibthorp, between Middleton Stoney and Audley in Oxfordſhire: Mr. Marſh, near Ford-End Farm, Bedford. In the counties of Suſſex and Surry Dr. Stokes ſays it is common. It flowers in july.

β. Bauhin notices a variety, with the leaves more deeply cut, the lower ones quite jagged. He ſays the flowers are paler, and ſometimes of a ſort of aſh colour. In Cluſius's figure, (2. 30. *f.* 2.) to which he refers, the leaves are not at all jagged.

γ. Whether the S. agreſtis of Lin. amoen. be the ſame with that of Villars I know not. The latter gives it as a ſpecies doubtingly; and deſcribes it as a foot high; the calyx and corolla both very clammy, occaſioned by a great number of golden glands, viſible with a glaſs. The upper lip of the corolla is almoſt ſtraight; the piſtil is longer than that by half; the lower lip is trifid, the middle ſegment rounded, a little concave and emarginate, the two lateral ones are ſhorter,

narrower,

[x] Jacquin. [y] Hort. kew. [z] Scopoli. [a] Hort. kew. [b] Willdenow. [c] Linn. ſpec. [d] Hort. kew. [e] Linn. ſpec. [f] Retz. [g] Hort. kew. [h] Jacquin. [i] Hort. kew. [k] Scopoli. [l] Linn. ſyſt. Engl. bot.

Digitized by Google

harrower, and rolled back. Corolla blue, ſeldom red. In S. pratenſis the leaves are more elongated, and the upper lip of the corolla is ſickle-ſhaped; but in low warm ſituations it approaches to the *agreſtis*.

25. This is a handſome plant. Leaves cordate-oblong, wrinkled, ſomewhat villoſe; the lower ones blunt, petioled, running down the petiole, unequally ſinuate-toothed, frequently eroſe-laciniate, the ſegments acute, unequal; the upper ſtem-leaves connate, ſeſſile, acute. Stem pubeſcent, with blunt angles. Flowering branches rod-like, erect, pubeſcent, eighteen inches high, and even more. Whorls commonly ſix-flowered, approximating. Bractes ovate-lanceolate, acuminate, bent down, pubeſcent, longer than the pedicels. Flowers nodding both before and after flowering. Calyx ſtriated, glandular-hairy, five-toothed or two-lipped; the upper lip three-toothed, the lower two; the middle upper tooth very ſhort. Corolla the ſame ſize as in S. pratenſis, (according to Willdenow, of the ſame colour, but double the ſize and more elegant:) upper lip ſickle-ſhaped, violet-blue, villoſe, often dotted with white; the lower lip white: the lateral lobes more produced, and acuminate; the middle lobe very large, bagged, ſometimes emarginate. Filaments bowed, on very ſhort pedicels. Style very long, ſtanding out. Stigmas acute. Seeds brown, even, roundiſh. According to Willdenow, the upper lip of the corolla is compreſſed and emarginate; the middle ſegment of the lower lip ſnow-white, two-lobed, concave, aſcending.

Native of Barbary, in the corn fields about Tlemſen; flowering early in the ſpring. Willdenow marks it as perennial. Desfontaines as biennial. According to the latter, in gardens the lower leaves are not eroſe but crenate-ſinuate [m].]

26. Lower leaves heart-ſhaped, acutely crenate, of a thick conſiſtence, ſeven or eight inches long, and four broad at the baſe, where they are eared. Stem four feet high, having two or three pairs of ſmaller leaves on the lower part at the joints. The upper part, for the length of two feet, has whorls of flowers, at two or three inches diſtance from each other, without any leaves under them. Calyx hairy and blunt. Helmet of the corolla arched, erect and blue, terminating in a blue point; the two ſide ſegments of the under lip are of a violet colour; the middle ſegment, which is indented at the point, is white, and curiouſly ſpotted with violet on the inſide; the two ſide lobes turn yellow before the flower drops.

[Stem herbaceous, blunt at the corners, white with hairs, as are alſo the petioles. Leaves oblong, wrinkled, almoſt naked, hairy beneath. Floral leaves cordate, ſeſſile, entire, acute, ſmall. Calyx compreſſed a little: upper lip three-toothed, the middle tooth ſomewhat ſmaller; the lower lip two-parted, hairy, clammy. Corolla large, blue: the upper lip ſickle-ſhaped, compreſſed, emarginate; the lower trifid, the middle ſegment large, bagged, two-lobed; with a whitiſh baſe; the lobes have violet ſpots, with a white border, which turns yellow; the lateral ſegments are horizontal, lanceolate, ſtretched out, and folded back; ſo that the lower lip in ſome degree reſembles a bee [n].

Native of India. Cultivated in 1731, by Mr. Miller [o]: and yet even now, ſays Mr. Curtis, this magnificent plant is rarely ſeen in our gardens. This perhaps may be owing to its being conſidered as a hardy plant, and yet requiring ſome care to be taken of it in ſevere winters. It flowers from may to july.

27. Stem, towards the root, ſuffruticoſe, erect, ſubdivided, ſtriated, pubeſcent; branches ſpreading, both they and the ſtem ſquare. Leaves acuminate, bluntly angular at the baſe, crenate-toothed, wrinkled, hiſpid above, ſubhirſute beneath. Petioles quadrangular, pubeſcent. Flowers terminating, in whorls, peduncled, blue. Whorls ſix-flowered, remote; bractes minute, linear, under the whorls. Calyx tubular, a little gibbous, ſtriated, compreſſed, hairy; mouth two-lipped, lower lip two-toothed, upper entire, erect. Hairs terminated by very minute blue glands. Upper lip of the corolla ſhort, emarginate; lower longer, trifid, the middle ſegment emarginate, whitiſh in the middle at the bottom of the tube. Style longer than the upper lip. Seeds oblong, naked, black and ſhining.

Common in the Weſt Indies, in fields and coppices. A ſpecimen in the Linnean herbarium creates a ſuſpicion that this is ſcarcely diſtinct from S. ſerotina [p].]

According to Miller, it is an annual plant, three or four feet high, with leaves of a bright green colour, on long ſlender footſtalks. The flowers in cloſe ſpikes at the ends of the branches of a fine blue colour; appearing in july.

[It is marked by Willdenow as perennial. Swartz does not inform us whether it is ſo, or annual.

28. Root perennial, brown, the thickneſs of the middle finger, ſtriking deep into the earth, and furniſhed with numerous fibres. Stems nearly upright, two feet high, ſet with horizontal ſomewhat viſcid hairs, purpliſh eſpecially at the joints. Root-leaves on long petioles, varying in form, oblong, rounded at the end, ſometimes a little pointed, not unfrequently heart-ſhaped at the baſe, but more commonly the leaf runs down on each ſide the footſtalk, and to a greater length on one ſide than on the other, very ſlightly hirſute, on the margin irregularly waved and ſerrate or toothed, paler beneath, veiny and marked with ſmall glandular concave dots: ſtem-leaves ſomewhat remote, the lowermoſt on ſhort footſtalks, the uppermoſt ſeſſile. Flowers in whorls, almoſt naked, containing about ſix flowers. Bractes cordate, acuminate, turned down, ſhorter than the flowers. Calyx purpliſh, ſlightly viſcid: upper lip obovate, moſtly terminated by a ſhort point, marked with three ribs, thoſe on the ſide much ſhorter than the middle one; lower lip almoſt ribbed, cloven nearly half way down; ſegments ovate-lanceolate, pointed, curved up. Corolla violet-coloured, a little longer than the calyx. Anthers oblong, black. Seeds black [q].

This and pratenſis are the only ſpecies of Salvia which are indigenous of Britain. It is ſmaller than that, but more aromatic, and of a deeper green. The ſtem is decumbent at the baſe. Bractes much larger in proportion to the flower; which is much ſmaller, and of a dark blueiſh purple [r]. The bractes are longer than the calyx, which is much wider than the tube of the corolla, but its ſegments do not ſpread open [s].

Native of all the four continents. Not uncommon in England, eſpecially on chalky and gravelly ſoils. Mr. Curtis has often remarked it in church-yards. The famous Cluſius, being in England in 1579, obſerved it about Greenwich, flowering and bearing ſeed in ſeptember. It flowers indeed during the whole ſummer from june, and even in october.

The herb and flowers prove very aromatic when rubbed. The ſeeds are ſmooth, and produce a great quantity of ſoft taſteleſs mucilage when moiſtened, whence they become ſerviceable for removing extraneous matter from the eyes. If put under the eyelid for a few moments, the tears diſſolve their mucilage, which envelops any ſand or duſt that may be in the way, and brings it out ſafely [t]. Hence ſome old writers have called it *Oculus Chriſti*; and others of our own country have ridiculouſly enough derived our Engliſh name *Clary* from the ſame circumſtance.

29. Native of the Cape of Good Hope; where it was found by Thunberg and Maſſon. The latter introduced it in 1774. It is ſhrubby, and flowers here moſt part of the ſummer [u].

30. This alſo was found at the Cape by Thunberg [x].

31. This has the herb of S. verbenaca, with the leaves of S. ceratophylla, and is a dwarf. Stems blunt, villoſe, aſcending, a ſpan high: with two branches commonly at top. Leaves oblong pinnate-ſinuate, crenate, blunt, petioled, two or three pairs on the ſtem. Spike truncate, with the whorls remote. Bractes cordate, three-flowered. Calyxes with glutinous hairs, and the upper lip plaited. Corolla violet-coloured,

[m] Desfontaines and Willdenow. [n] Linn. mant. [o] Hort. kew. [p] Swartz. [q] Curtis. [r] Smith. [s] Withering. [t] Engl. bot. [u] Hort. kew. and Linn. ſuppl. [x] Linn. ſuppl.

Digitized by Google

ſcarcely twice as long as the calyx, with the middle lobe of the lower lip white [y].

Leaves tomentoſe underneath, bent back at the edge; the pinnules ſublinear, diſtinct, unequal, blunt, unequally toothed. Stem upright, branched at bottom, hirſute. Whorls approximating, ſix-flowered. Flowers ſubſeſſile. Bractes ovate, ſhorter than the calyx; which is ſhort and hirſute, with the upper lip compreſſed rounded emarginate, the lower two-toothed, the teeth acuminate. Corolla blue, nearly three times as long as the calyx. Barrelier's figure has the leaves leſs deeply pinnatifid, and the pinnules wider [z].]

The lower leaves are upwards of four inches long, and not more than an inch broad, regularly ſinuate on both ſides. The ſtalks riſe about the ſame height with S. Verbenaca, but all the leaves upon them are ſinuate; the flowers alſo are ſmaller.

[Native of Italy, and of Barbary near Caſſa, if it be the plant of Desfontaines, whoſe deſcription differs in ſo many circumſtances from that of Linneus.—Cultivated in 1768, by Mr. Miller. It flowers from may to july, and is biennial [a].

32. This ſpecies riſes with a ſingle ſtem about a foot high, tetragonal, and about the thickneſs of a quill: radical leaves ovate, varying occaſionally in their form, being more or leſs broad, and either ſharp-pointed or obtuſe, crenated, and almoſt pinnatifid; wrinkled, of a deep green, and very ſmooth; but pale and villoſe beneath. Cauline leaves ſimilar, but much ſmaller, and very few in number: they are alſo ſeſſile. Flowers white or very pale yellow, and of moderate ſize [b].

Native of Auſtria, Hungary and Moldavia.—Introduced in 1776, by Joſeph Nicholas Jacquin, M.D. It flowers in june and july [c].

33. Native of the Pyrenees.

34. The whole plant is pubeſcent with villoſe hairs glutinous at the tip. Leaves wrinkled, pubeſcent. Bractes cordate, villoſe, ſharpiſh, generally ſhorter than the calyx. Upper lip of the calyx three-toothed, equal; lower bifid, acute. Upper lip of the corolla erect; lower concave, with the lateral ſegments ſtretched out. Anthers ſtanding out. Style white [d].

Retzius aſſerts, that with him the leaves are ovate, and not cordate: but that when the plant is kept conſtantly in the hot-houſe, they approach nearer to a cordate form, and the plant is luxuriant with very long looſe branches. The racemes are quite ſimple, with far-diſtant whorls, and the whole plant has a pleaſant but powerful ſmell. When kept in a pot in a green-houſe, and ſet out in ſummer, it is much ſmaller, upright, hard, has leſs ſmell, the leaves are narrow, and the flowers are in a brachiate panicle, with the whorls leſs remote.

Native of Syria. Introduced in 1773, by Chevalier Murray. It flowers in july.

35. This approaches very near to the preceding, and indeed ſcarcely differs from it, except in its ſhort ſtamens reaching up only to the throat or aperture of the corolla, which is white.

Native of the Cape of Good Hope, where it was found by Maſſon, and introduced in 1775. It flowers in july and auguſt [e].—It is marked as ſhrubby, whereas the *S. diſermas* is marked only as perennial.

36. Stem a foot and half high, and a thumb's thickneſs at bottom, but gradually tapering in its aſcent, quadrangular, and hollowed on the ſides, ſlightly villoſe with horizontal hairs: branches oppoſite, and croſſwiſe; leaves ovate-lanced, cordate, much wrinkled, and unequally double-crenate: the radical leaves are footſtalked, the cauline ſeſſile: ſpike terminal on the ſtem and branches, decompounded, and viſcous: ſpikelets ovate, conſiſting of ſix-flowered approximating whorls, on a common quadrangular footſtalk: calyx ſtriated, hairy, and blue-green above: flowers about the ſize of thoſe of S. ſylveſtris, and of a pale blue colour, and marked within by three deep blue lines [f].

[y] Linn. ſpec. and ſyſt. [z] Desfontaines. [a] Hort. kew. [b] Jacquin. [c] Hort. kew. [d] Linn. mant. [e] Hort. kew. [f] Murray.

Native of Africa. Introduced in 1784, by Monſ. Thouin. It flowers in june and july [g].

37. Height about two feet: upright, obtuſely quadrangular; channelled on the ſides, branched: lower branches very ſhort, the others longer, all ſpreading: leaves firm, wrinkled, hairy, crenate-toothed, ſubundulated, very ſpreading, the loweſt longer than the the reſt, ſinuated and ſublyrated towards the baſe; the middle ones ovate, ſinuate-angular, obtuſe, and ſtanding on ſhort footſtalks; the uppermoſt cordate, ſeſſile, pointed, and recurved: ſpikes terminal, verticillated, and either ſimple or compound: whorls remote, horizontal, with three flowers on each ſide: bractes ovate, ſharp-pointed, hairy, and of a browniſh-green: calyx ciliated on the edges: flowers ſmall, blue, with a narrow tube, and ſhort helmet: ſtamens ſhorter than the helmet.

Suppoſed to be a native of Egypt [h].]

38. Stem ſhrubby, eight or ten feet high, ſending out ſlender four-cornered branches of a purpliſh colour. Leaves thin, pale green, and hairy on their under ſide, on long ſlender footſtalks. Flowers in cloſe thick ſpikes at the end of the branches. Corolla of a fine blue colour.

[Stems thick, a fathom high, four-grooved, with the corners rounded, ſubpubeſcent, whitiſh. Leaves ovate-acute, ſerrulate, ſoft, three inches long, whitiſh beneath: petioles ſhorter than the leaves, biglandular on the outſide at the baſe; the glands callous. Flowers in long, denſe, interrupted ſpikes, compoſed of many-flowered whorls. Calyx ſtriated, ſmooth; upper lip entire, lower bifid, with the points ſubulate. Corolla deep blue, much longer than the calyx [i].

Native of Mexico. Cultivated in 1724, by James Sherard, M.D. [k] But it did not flower in the Eltham garden till november 1729. Cavanilles ſays, that it flowers in the Madrid garden in december; and Mr. Miller, that it makes a pretty variety in the green-houſe by flowering in the winter ſeaſon. In the Kew catalogue it is marked as flowering from may to july.

39. Stem ſuffruticoſe, bluntly four-cornered, rough-haired. Leaves cordate-oblong, cloſely ſerrate, wrinkled, green and rough-haired above, very cloſely woolly and white beneath. Petioles angular, rough-haired, ſcarcely the length of the leaves. Raceme terminating, almoſt upright. Whorls rather remote, compoſed of about ſix flowers, without any bractes. Peduncles ſcarcely ſo long as the calyx, ſpreading, round, rough-haired, one-flowered. It is ſingular in this ſpecies, that one or two flowers in each whorl expand at the ſame time, and not thoſe of the loweſt whorl firſt, and then the next ſucceſſively. Calyx bell-ſhaped, angular, rough-haired, coloured at the tip, rugged within; upper lip entire, acute, with the point curved in; the lower bifid. Corolla twice as long as the calyx, of a very lively violet colour: upper lip arched, blunt, entire, denſely bearded on the outſide, naked only at the margin; lower three-lobed, pubeſcent on the outſide; palate wrinkled, ſmooth, pale. Stamens ſhorter than the corolla. Style ſtanding out, curved in, violet, rough-haired. Segments of the ſtigma ſpreading, acute, ſmooth. Seeds obovate, ſmooth.

There is no ſmell or aromatic taſte in the dry plant, but the leaves are almoſt as bitter as the roots of Gentian.—Native of New Granada [l].

40. Stems three feet high, ſomewhat rugged, reclining at bottom and then upright; branches ſpreading a little and then turning up, oppoſite. Leaves almoſt equal, on channelled petioles. Flowers in terminating ſpikes, compoſed of ſix-flowered whorls. Stipules ſhort, acute, ſoon falling. Calyx bell-ſhaped, ſmooth ſtriated; upper lip entire, ovate-mucronate; lower bifid at the tip. Corolla an inch and half long, of a deep and very fulgid ſcarlet colour, paler within: upper lip elongated, entire; lateral ſegments of the lower lip ſhorter, revolute, the middle one wide plaited with an orbicular three-notched diſk. Filaments ſhorter

[g] Hort. kew. [h] Murray. [i] Cavanilles. [k] Hort. kew. [l] Smith.

Digitized by Google

by half than the corolla, white; anthers ovate, whitiſh. Germs ovate, ſet in a ſquare receptacle, to which adheres in front a longer acute membrane, covering the two forward germs. Style wider at top, compreſſed, bearded. Stigmas revolute, fleſh-coloured, ſtanding out. Seeds obovate.

Native of Mexico, flowering in the royal Madrid garden from october to february[m].

41. Stem ſuffruticoſe, the height of a man, upright, brachiate, ſomewhat knotty, looſely chapped, aſh-coloured. Branches and branchlets oppoſite, ſpreading, four-cornered, naked at the baſe, rufous: ſhoots four-grooved, green at the top, clammy. Leaves ſpreading, acute (in the garden bluntiſh,) crenate-ſerrate, ſomewhat wrinkled, veined, with the midrib and veins prominent only beneath, ſubcoriaceous, greeniſh but paler on the back. Petiole ſcarcely half as long as the leaf, round on one ſide, grooved on the other. Flowers very many, from the axils of the ſhoots, in a ſort of whorl, in the garden commonly five together, the two lower of which are later: they are on ſhort, ſpreading one-flowered peduncles, jointed at the top. Bractes ſome, two of them larger, one from each ſide, like ſtipules, leafy, linear, acute, reflex. Calyx nerved, ſtriated at the baſe: upper lip erect, acuminate, flat; lower of the ſame ſhape, but two-parted. Corolla ſcarlet, an inch and half long, ſcarcely papilloſe to the view: tube angular, tubercled and ventricoſe at bottom, longer than the calyx: upper lip ſtraight, elongated, ſcarcely emarginate, denſely bearded, concealing the ſtamens and ſtyle by its converging ſides; lower lip hanging down at a right angle, roundiſh, blunt, trifid, villoſe, the lateral ſegments blunt, the outmoſt wide, ſhort, emarginate or repand. Filaments ſhort, curved in: rudiments of a third and fourth filament are inſerted into the tube above. Anthers linear, compreſſed, peltate, one-celled, ſcarlet. Germs indiſtinctly girt with a fleſhy receptacle. Style compreſſed, bearded at the tip and ſcarlet. Stigma naked, ſtanding out beyond the helmet, ſcarlet; the ſegments ſubulate, very long, reflex, the upper one longer and acute, the lower bluntiſh. Calyx ſcarcely increaſed, but ſhrivelling in ſeeding time. Seeds oblong, compreſſed, erect, approximating, brown.

Native of Peru, where it was found in the province of Huanuco, near the head of the river of Amazons by Dombey, who ſent the ſeeds to the Paris garden[n]. It was introduced at Kew in 1783, by Monſ. Thouin; and flowers moſt part of the ſummer[o].

According to Cavanilles, this may be diſtinguiſhed from the *fulgens* by having the ſtem hard and ſhrubby; the leaves ſmooth, ſhining, and ſomewhat coriaceous; the flowers ſhorter and leſs fulgid. Dombey, who firſt found it, with Pavon and Ruiz, named it *Salvia pyrifolia*; and the younger Linneus, who ſaw it when he was at Paris, gave it the name of *S. leonuroides*, which Gloxin has adopted.

The latter author remarks a ſingularity in the inflorescence of this ſpecies, that the flowers are not in a terminating raceme, ſpike, or panicle, as in the others, but in ſeparate whorls from the axils of the leaves, without any proper bractes. The ſize, villoſity and colour of the corolla are ſtriking circumſtances, the ſtraightneſs of the upper lip, and the peculiar appearance of the lower lip. The upper lip of the calyx being entire, is common to this but with few of the ſpecies, as *mexicana* and *hiſpanica*; the former of which, on this very account, was ſeparated by Heiſter from the Salvias, and made a new genus, under the name of *Jungia*. *S. formoſa* is allied to this in having the tube of the corolla twice as long as the calyx, the upper lip ſtraight, ſomewhat ſickle-ſhaped, and villoſe, the ſtyle longer than the corolla and hirſute; but then the *mexicana* has ſix-flowered whorls forming a raceme, and ovate leaves, acuminate at both ends, ſerrate except at the baſe[p].

42. Stem ſuffruticoſe, ſtriated, villoſe at top. Leaves ſmoothiſh above, paler beneath and hairy along the nerves and edges. Petioles ſhorter than the leaves, hairy. Spike terminating, whorled, erect. Two flowers commonly in each whorl. Bractes oppoſite, ovate, mucronate, nerved, hairy, deciduous. Peduncles filiform, ſhorter than the calyx, denſely woolly, one-flowered, all directed the ſame way. Calyx ſcarcely ventricoſe, nerved, woolly on the outſide, rugged within; the three ſegments nearly equal, acute. Corolla three times as long as the calyx, curved in, ſcarlet, hairy on the outſide; border bifid, the ſegments nearly equal, ſcarcely ringent. Stamens ſtanding out very far beyond the corolla, ſmooth. Anthers incumbent. Style the length of the ſtamens, ſmooth. The two ſegments of the ſtigma are acute, recurved, ſmooth. The dried leaves are ſcarcely aromatic, and not very bitter. Salvia coccinea, formoſa, tubiflora and amethyſtina are all allied to tubiflora, but yet very diſtinct ſpecies.—This is a native of Lima in South America. Dombey and Thouin[q].

43. This reſembles the preceding, but the leaves are ovate and ſoft, the corollas narrower and pubeſcent, the lower lip reflex, and the ſtamens ſhorter. The corolla is ſcarlet in both.—Native of Mexico[r].

44. Leaves exquiſitely cordate, petioled. Calyxes funnel-form, ſlender, ſcarcely rough-haired. Corollas very beautiful ſcarlet[s].

Native of Eaſt Florida; where it was found by Mr. John Bartram, and cultivated here in 1774. It flowers moſt part of the year[t].

45. This reſembles the preceding, but the leaves are ovate, ſmoothiſh, unequal at the baſe; the ſtem is hairy, the corollas longer, widening at the throat.—Native of South America[u].

46. Root annual. Stem a foot and half high, blunt at the corners, four-grooved, clothed at top with reflex white hairs. Leaves acute, wrinkled, ſerrate, acute at the baſe. Spike ſquare, with ovate bractes, the length of the calyxes and ciliate. Calyxes under each ſcale often five, three-toothed at the mouth, acute, the upper tooth ſingle. Corolla blue, with the border the length of the calyx; the helmet ſhorter and ſubvilloſe; the lower lip trifid, blunt, quite entire, with two pale ſpots at the baſe[x].

Native of Spain and Italy. Cultivated in 1739 by Mr. Miller. It flowers in june and july[y].

Gærtner remarks, that the ſeeds of various ſpecies of Salvia are mucilaginous, beſides thoſe of Verbenaca; as diſermas, argentea, ceratophylla, Æthiopis, urticifolia, canarienſis, &c. but that in hiſpanica, nutans, glutinoſa, and ſome others they are not ſo. He deſcribes the ſeeds of this ſpecies as elliptic, compreſſed like a lens, ſmooth and ſhining, aſh-coloured marbled with brown.

Miller has a S. hiſpanica, but it cannot be this: neither is it to be found among his Horminums or Sclareas.

47. This riſes with ſeveral ſomewhat ſhrubby ſtems about a foot and half high, upright, tetragonal and hairy, branching from the boſoms of all the leaves: leaves oppoſite, the lower ones lyrated, obtuſe, and footſtalked; the upper cordate, ſeſſile, and more acute: all rugoſe, villoſe, and crenated. Whorls ſix-flowered, at firſt approximated, and afterwards becoming more remote in conſequence of the elongation of the branches: bractes cordate, pointed, ſeſſile, and purple: calyx hairy, purpliſh brown: corolla deep violet-purple: ſmell of the whole plant unpleaſant[z].

Native of Africa. Introduced in 1775, by James Bruce, Eſq. It flowers in june and july[a].]

48. This ſends out from the root a great number of heart-ſhaped leaves, ſerrate, deeply veined, upon pretty long foot-ſtalks which are hairy. From among theſe ariſe the ſtalks, two feet and a half high, having at each joint two leaves which are alſo heart-ſhaped, and half embrace the ſtalk. At the two or three upper joints a long flowering-ſtalk comes out on each ſide: theſe, as well as the principal ſtalk, have whorls of ſmall blue flowers, not much unlike thoſe of the S. verbenaca, but larger. The ſpikes are more than a

[m] Cavanilles. [n] L'Heritier. [o] Hort. kew. [p] Gloxin, p. 18, 19.

foot

Digitized by Google

foot long, and towards the top the whorls are nearer together.—Native of Germany and Auſtria.

β. This has ſome reſemblance to that juſt now deſcribed, but the lower leaves are cut at the baſe to the midrib, into one or two pairs of ears or lobes, which are ſmall, and often at a diſtance from each other; the leaves are not ſerrate, but bluntly indented. The ſtalks of this are more ſlender, and do not grow ſo tall, nor are the ſpikes of flowers ſo long.

Native of the South of France and Italy. [Cultivated in 1683, by Mr. James Sutherland. It flowers from june to november [b].

49. This ſpecies bears ſo near a reſemblance to S. verticillata as to be with ſome difficulty diſtinguiſhed, except when in flower; the corolla differing conſiderably from that of the verticillata; being of a deep purple, with the upper lip cordate-emarginate, obtuſe, and ſpreading: the lateral diviſions of the lower lip ſubovate, ſpreading, and of the ſame length with the upper, but the middle one longer, and very obtuſe.

Suppoſed to be a native of the warmer parts of the globe [c].—Introduced in 1776, by Joſeph Nicholas de Jacquin, M.D.[d]]

50. This has an abiding root, compoſed of ſtrong woody fibres. Leaves four inches long, and three broad at the baſe, of a pale yellowiſh green colour, upon foot-ſtalks three or four inches long. Stems ſtrong, near four feet high, having ſmaller leaves below, and the upper part cloſely ſet with whorls of large yellow flowers. The whole plant is very clammy, and has a ſtrong ſcent ſomewhat like common garden Clary. The flowers are uſed in Holland to give a flavour to the Rheniſh wines.

[Calyx three-lobed. Corolla ſickle-ſhaped, yellow dotted with brown: the middle lobe of the lower lip crenate [e].

Native of Germany, Auſtria, Switzerland, Italy and the South of France.—Cultivated by Gerarde in 1596. It flowers from june to november [f].

51. Native of Spain.—Leaves large, hairy. Stems upright, three feet high. Flowers large, blue, in diſtant whorls. Seeds round, browniſh [g].]

52. Stem ſhrubby, five or ſix feet high, dividing into many branches covered with a flocky down. Leaves three inches and a half long, and an inch and half broad at the baſe, where are two acute angular ears; petioles long and woolly. The top of the ſtalk branches out into many foot-ſtalks, forming a ſort of panicle. The flowers are of a light blue colour, and are ranged in whorled ſpikes, having two ſmall leaves under each whorl.

[Calyx five-cleft, hiſpid: the upper ſegment larger, blunt, trifid; the lower two-parted [h].

Native of the Canary Iſlands. Cultivated in 1697, by the Dutcheſs of Beaufort. It flowers from june to ſeptember [i].

53. Native of the Cape of Good Hope: obſerved there by Thunberg.]

54. This riſes with a ſhrubby ſtalk four or five feet high, dividing into branches. Leaves ovate, of a gray colour. The flowers come out in whorls towards the end of the branches; they are of a fine blue colour, larger than thoſe of the common Sage, appear in ſucceſſion moſt of the ſummer months, and thoſe which come early are often followed by ſeeds ripening in autumn.

Native of the Cape of Good Hope. [Cultivated in 1739, by Mr. Miller [k].]

55. This riſes with a ſhrubby ſtalk ſeven or eight feet high, covered with a light-coloured bark, ſending out branches the whole length which grow almoſt horizontally. Leaves of a gray colour. Flowers in thick ſhort ſpikes at the end of the branches; they are very large, and of a dark gold colour.

[Calyx bell-ſhaped, three-lobed, villoſe at the baſe [l]. The leaves are nearly round, and have a pleaſing ſilvery hue, a few of them only [m], and thoſe chiefly at the extremities of the young ſhoots are of the form deſcribed in Linneus's ſpecific character. The colour of the leaves, the colour and unuſual magnitude of the corolla, are the moſt ſtriking features of the ſpecies.

It is called *aurea* from the colour of the corolla; *ferruginea* would have been more expreſſive, for though when it firſt opens it is yellow, yet it quickly and conſtantly becomes of the colour of ruſty iron [n].

Native of the Cape of Good Hope. Cultivated in 1731, by Mr. Miller. It flowers from may to november [o].]

56. This has great reſemblance to *africana*, but the branches are ſtronger, and grow more erect; the leaves are longer and not ſo broad, and their edges are not ſerrate; the flowers grow in long looſe ſpikes at the end of the branches, they are larger and of a paler blue; their calyxes are broader, ſpread wider, and are of a pale blue colour.

[Stems ſix feet high, rooting at bottom. Leaves petioled, an inch long: the lower ſerrate, but ſeldom eared; the upper ones quite entire. Calyxes bell-ſhaped, with the ſegments rounded, finally becoming ſcarioſe, wide, blood-red.

Native of the Cape of Good Hope, on the ſandy coaſt [p]. Introduced by Mr. Miller from Holland before 1759.

57. Stem fruteſcent, erect, round, purpliſh, rugged. Leaves ſmall, wedge-form, ſharply toothed, veined, even, ſubpetioled. Panicle brachiate, decompounded. Calyxes trifid, ſcarcely hairy, with the two lower ſegments acute, the upper one three-toothed. Helmet of the corolla ſcarcely longer than the lip. Style longer than the corolla [q].—Native of the Cape of Good Hope.

Though Mr. Miller in his figures refers to the *africana* of Linneus, yet it is plain that he intended the *paniculata*, which he does not appear to have diſtinguiſhed from that, notwithſtanding he cultivated them both. This in 1758. It flowers from june to ſeptember [r].

58. This is a little ſhrub, with brachiate, narrow, even branches. Leaves petioled, toothed towards the baſe, tomentoſe underneath. Racemes at the diviſions of the ſtem, elongated, remotely whorled. Flowers on each ſide three, pedicelled. Bractes ovate, quite entire, acuminate, ſmooth, commonly ſmaller than the calyx; which is ſpreading-bell-ſhaped, like that of Moluccella or Marrubium Pſeudodictamnus, with a five-lobed border: the two upper lobes wider, hairy on the outſide. Corolla whitiſh, larger than the calyx: the upper lip bifid, patulous, (not ſickle-ſhaped or elongated;) the lower trifid, with the middle ſegment larger. Stamens the length of the corolla; but the ſtyle twice as long.—Native of the Levant.

59. Stem a foot high, obſcurely quadrangular, hirſute, brachiate. Leaves petioled, ſubcordate or ovate, wrinkled, bluntiſh, more hairy beneath; the upper ones ſeſſile, acuminate, ſerrate-crenate. Bractes nerved, ſmooth above, quite entire, awned. Whorls three-flowered on each ſide, ſeſſile. Calyx tubular, grooved, awned, almoſt equal, with three upper teeth cloſer together, and two lower. Corolla white: helmet erect, ſubfalcate, emarginate, the length only of the lower lip; which is trifid, with the middle ſegment concave, two-lobed, and the lateral ones bent down. Stamens white, longer than the helmet. Anthers yellow. Style purple. Calyx of the fruit dry, compreſſed, ſtriated, the length of the bractes, with awl-ſhaped teeth, pungent as in Hyoſcyamus, within the bractes at the whorls. Involucrets two-leaved, ſhort, acute.—Native of Egypt; where it was found by Forſkahl [s].

60. Very nearly allied to the preceding, but ſufficiently diſtinct, by its fruteſcent ſtem, cordate eroſe-toothed wrinkled leaves, and ciliate bractes; it is beſides a very ſtinking plant.—Native of northern Africa [t].]

61. Common Clary has the lower leaves large, in good ground ſeven or eight inches long, and four

broad

Digitized by Google

broad at the base, ending in blunt points. Stems large and clammy, about two feet high, with leaves of the same shape, but smaller, and sending out small opposite side branches. Flowers in loose terminating spikes, composed of whorls, of a pale blue colour. It is a biennial plant native of Syria [and Italy, Dauphiné, &c.—It was cultivated here in 1562, as appears from Turner's herbal, and flowers from july to september [t].

The whole plant has a very strong scent. It was formerly used in medicine, but is now neglected. A wine is made from the herb in flower boiled with sugar, which has a flavour not unlike Frontiniac.

62. This plant is very beautiful from the number and size of the flowers, the spike of which is terminated by bractes complicated into a pale rose-coloured strobile. It differs from the rest in the size of the bractes, in its long compressed tube, and its dense terminating great-flowered spike.—Native of Mexico [u].]

63. This is a biennial plant. Leaves very thick and woolly, eight or nine inches long, narrow, cut into obtuse segments nearly opposite on their sides almost to the midrib, somewhat like a stag's horn in shape, and spreading flat on the ground. Stem more than a foot high, thick and very woolly, sending out branches by pairs, and having long narrow leaves in pairs at each joint, which are serrate. Flowers in loose whorled spikes, at the top of the stalks barren. Corolla white.

[Bobart describes it as ochroleucous or pale yellow, or brimstone-coloured. Seeds large, rounder than in most of the other species.

Native of Persia, where it was gathered by Rauwolff. It was sent by Huntingdon from Aleppo, and was cultivated several years (before 1699) in the Oxford botanic garden. It flowers in july and august [x]. Its being sent from Aleppo, probably gave occasion to Mr. Miller to set it down as a native of Syria.]

64. Leaves of a thick substance and very woolly, especially on their under side, the upper side rugged and wrinkled, with several longitudinal veins diverging from the midrib. Stems about two feet high, sending out many branches in pairs. Flowers in whorled terminating spikes: under each whorl two hollow green leaves shorter than the calyx. Under lip of the corolla white, upper pale blue.

[Stem upright, firm, clothed with white wool, single at bottom, but divided above into numerous panicled branches. Root-leaves procumbent, ovate, petioled, sinuate, crenate, very much wrinkled, woolly, white, blunt: upper stem-leaves sessile, toothed, acute: the uppermost sometimes bent back. Bractes concave, nerved, converging, roundish, mucronate, shorter than the calyx, woolly or subvillose. Whorls four or six-flowered. Flowers on short pedicels. Calyx whilst young woolly, striated, five-toothed, the teeth ending in a little prickle; but when the fruit is ripe, closed and compressed. Corolla white, pubescent: upper lip narrow, sickle-shaped; lower three-lobed, the side lobes very small, the middle one excavated, emarginate; or as Linneus describes it cohering in front and forming a bag. Anthers yellow. Seeds brown, even, compressed a little on one side, and subtriquetrous on the other [y].

It is a biennial plant, native of France, Austria, Illyria, Italy, Greece and Africa. It was cultivated in 1570, according to Lobel, and flowers in may and june [z].]

There are two varieties of this, one with very broad embracing leaves, slightly indented on the sides; the other with longer leaves deeply jagged.

[γ. Has the leaves nearly of the shape of Betony, but more deeply sinuate towards the base, soft and lanuginose. Stems branched, a cubit high. Flowers few in a whorl, white. It came from Aleppo [a], See n. 78.

65. This differs from the preceding, in having the stem almost always quite simple, in its clamminess, in its narrow bractes, with the leaves not bent back at the tip, and its unarmed calyxes. It is distinguished from S. argentea, by having narrower leaves, not at all erose or tooth-angular, the stem not panicled, and by the colour of the flowers.—Native of Spain, in the mountains about Siguenza [b].]

66. Leaves of a thick consistence, having several irregular indentures on their borders. Stem near a foot and half high, sending out two or four branches near the bottom, which grow erect. Whorls of flowers large, towards the top barren. Corollas white.

[It is a middle species between *Sclarea* and *Æthiopis*. Leaves erose, in the barren herb very tomentose. Panicle less brachiate, pubescent, clammy, with the ends of the branches barren, as it were spiny. Bractes concave, awnless. Corolla white, with the helmet purplish and pubescent, and the lip yellowish. Style longer than the corolla [c].

Native of the island of Candia. Biennial. Cultivated in 1768, by Mr. Miller [d];] who says that it is a native of Sicily, as well as of the Archipelago; that in dry soils it will live several years; that it flowers in june, and that the seeds ripen in the beginning of august.

[67. Stem pubescent at top and roundish. Lower leaves quinate-pinnate, the upper ones ternate. Lateral leaflets petioled lanceolate blunt veined quite entire pubescent on both sides: terminating leaflet twice as large as the others oblong blunt veined pubescent on both sides. Flowers whorl-spiked terminating naked. Bractes ovate acuminate quite entire.—Native of the Levant. Shrubby [e].]

68. This is an annual or biennial plant, with trailing stalks. The lower leaves are composed of two or three small pairs of leaflets, terminated by one large leaflet; those higher up are trifoliate, with the terminating leaflet four times the size of the side ones. Flowers in whorls, large, both corolla and calyx of a deep blue colour.

Stem hairy. Calyx ovate, hirsute, inflated; the mouth compressed without teeth. Corolla not sickle-shaped small purple [f].

Native of the Levant. Cultivated 1739, in the Chelsea garden. It flowers in july [g].

69. Lower leaves pinnate, upper ternate, with the end leaflet larger, equally serrate, on long petioles, the upper ones often simple. Flowers in whorls, large, flesh-coloured. Seeds round, black [h]. It resembles the following species, but is distinct in the form of the leaves, the structure of the flowers, and the long lanceolate bractes [i].—Native of the Levant.

70. Stem suffruticose low round hoary with a few white hairs scattered over it. Common petiole channelled. Leaflets five petioled obovate serrate towards the tip, nerved, the end leaflet a little larger. Flowers in whorls forming a terminating spike; the lower whorls supported by two bracte-shaped entire leaves. There is besides a single proper bracte to each flower, ovate acute entire hoary shorter than the calyx. Calyx striated two-lipped ringent, with the upper lip three-toothed, the lower deeply divided, with the teeth spiny. Corolla purple, twice as long as the calyx; the throat ventricose, the upper lip arched emarginate villose on the outside, the lower widened and waved.

Native of Armenia, where it was gathered by Tournefort [k].

71. This differs from S. pinnata, to which it is allied, in having the lower leaves bipinnate, the plant naked and smooth below, the flowers panicle-whorled. Native of Japan. Annual [l].

72. This is an intermediate species between S. clandestina and ceratophylla. Native of Sicily, and Egypt, where it was found by Forskahl. Biennial [m]. Introduced in 1771, by Monf. Richard. It flowers from june to september [n].

73. Stem of the second year flowering, erect, a foot and half high, leafless, with whorls beyond the middle. Branches two, opposite, below the lowest whorl. Root-leaves ovate, lyrate, with a smaller lobe at the

[t] Hort. kew. [u] Cavanilles. [x] Mor. hift. and hort. kew. [y] Desfontaines. [z] Hort. kew. [a] Mor. hift.

base

base on both sides, repand-crenate, blunt, villose, green. Bractes shorter than the calyx, cordate, acute, quite entire. Whorls on each side with three or five flowers, on short peduncles. Calyxes with clammy hairs scattered over them. Corolla blue, three times as large as the calyx: helmet sickle-shaped, semibifid with the lobes incumbent; lip three-lobed, with the middle one two-lobed, larger, crenate, netted at the base with blue dots. Style twice as long as the corolla. It has the appearance of the next species.—Native of the Levant; where it was found by Forskahl.

74. Native of Russia. Introduced in 1780, by Peter Simon Pallas, M. D. It flowers from june to september[r].

75, 76. Both supposed to be natives of the empire of Russia.

77. Stem upright, hirsute, with blunt angles. Branches long, rod-like, upright. Leaves smooth; the lower ovate-oblong, blunt; middle and upper few, sessile, lanceolate, acute, often quite entire. Two, four or six flowers in a whorl, distinct, pedicelled, before and after they open nodding. Bractes ovate, acute, reflex. Calyx hirsute, striated, five-toothed; teeth bristly-spinose at the tip, the three upper ones shorter. Corolla blue, the size of S. pratensis; the upper lip villose, sickle-shaped, compressed; the lower three-lobed; the middle lobe largest, concave. It differs from S. bicolor in having ovate-oblong crenate leaves, not erose or sinuate-crenate. It is an annual plant, native of Algiers near Maiane.

78. This is a branched upright shrub. Branches villose, with blunt angles. Leaves petioled, crenate-toothletted, with the teeth sometimes sharp, sometimes blunt; the lower ones ending bluntly, the upper branch-leaves acutely. Whorls four or six-flowered. Flowers subsessile. Bractes cordate, concave, mucronate, hirsute. Calyx two-lipped, villose, with whitish dots frequently scattered over it, after flowering compressed on both sides and closed: the three upper teeth almost equal; the lower somewhat spiny. Corolla like that of S. pratensis, but white and only half the size: upper lip villose and bowing; lower three-lobed, the middle lobe excavated, emarginate. Stamens two barren, very small; two fertile, often standing out. Seeds roundish. The whole plant has a very strong smell.—Native of the kingdom of Tunis.

79. Allied to S. Æthiopis. Differs in the stem, branches, clammy calyxes villose not woolly, in the corolla being almost double the size; the upper flowers abortive. The leaves are almost tomentose, lying in a ring on the ground. But the leaves are sometimes almost smooth. The root is biennial[s].

This is probably the third Sclarea of Miller, which he says] has some resemblance of the second, (S. Æthiopis) but the leaves are larger, very woolly, and glutinous; they are oblong-ovate, deeply and sharply indented, and end with very acute points. The stalks are woolly, about two feet and a half high, sending out side branches by pairs; these terminate in loose spikes of whorled flowers, which are white, and the whorls are smaller than those of the other sorts.

Native of Portugal and Syria, also of Barbary. It was cultivated by Mr. Miller in 1743.

Mr. Miller has another species of Sclarea from Tournefort's corollary, which he names after that celebrated author. *S. orientalis* (n. 16). He describes it as having a perennial root, from which spring out many spear-shaped leaves about four inches long, and one inch and a half broad in the middle, of a dark green colour, serrate and ending in acute points. The stalks rise three feet high, sending out many branches by pairs their whole length, having leaves on them, which towards the top are sessile. The flowers grow in whorled spikes at the top, having no leaves under them; they are small, of a bright blue colour, and at the top of the spike are very deep blue flowers which are barren. These appear in july, and the seeds ripen in september.

Native of the Levant, where it was discovered by Tournefort, who sent the seeds to the royal garden at Paris, and compares the leaves to those of Betony, only that they are very sharp, and notices the purple coma. This also was cultivated by Mr. Miller in 1743.

He has likewise two species of Salvia not noticed by Linnæus, both found about Smyrna by William Sherard, when he was consul there: S. fruticosa, n. 5. and S. orientalis, n. 8.

PROPAGATION AND CULTURE.

All the sorts of Sage may be propagated by seeds if they can be procured; but as some of them do not perfect their seeds in England, and most of the sorts, but especially the common kinds for use, are easily propagated by slips, it is not worth while to raise them from seeds. The slips of the hardy sorts should be planted the beginning of april on a shady border, where, if they are now and then refreshed with water, if the season should prove dry, they will soon take root. When the slips have made good roots, they may be taken up with balls of earth, and transplanted where they are to remain, which should always be upon a dry soil, and where they may have the benefit of the sun: for if they are planted on a moist soil, or in a shady situation, they are very subject to be destroyed in winter; nor will these plants endure the cold so well, when planted upon a rich soil, as those which have a barren, dry, rocky soil, which is the case of most of the verticillate plants; for these will often grow upon walls, where, although they are more exposed to the cold than those plants in the ground, they are always found to remain in severe winters when the others are destroyed. The side shoots and tops of these plants may be gathered in the summer, and dried, if designed for tea, otherwise they are best taken green from the plants for most other uses.

The roots of the common sorts of Sage will last several years, if they are in a warm dry soil; but where they are often cropped for use, the plants will become ragged, so there should be a succession of young ones raised every other year.

Several of the sorts are somewhat tender, and will not live through the winter in the open air in England, therefore these must be planted into pots filled with fresh, light, sandy earth, and in winter they must be removed under a hot-bed frame, that they may have a great share of fresh air whenever the season is mild; for if they are too much drawn, they seldom flower well, and make but an indifferent appearance. In summer they must be exposed amongst other exotic plants in some well-sheltered situation, for they are pretty hardy, and only require to be sheltered from the frost. These plants must be often refreshed with water in warm weather, otherwise they will shrivel and decay; and they should be new-potted at least twice every summer, because their roots will greatly increase, which, if confined in the pots too long, will turn mouldy and decay.

Others, as the 1st, 27th, 68th, &c. are annual plants, only propagated by seeds; these may be sown upon a bed of light earth in the places where they are to remain. The seeds of the 68th sort should be sown in autumn, and then the plants will come up the following spring; but, if they are kept out of the ground till spring, the plants will not come up till the next year. Those of the 27th sort may be sown the beginning of april upon a warm border, where the plants will appear in may, and require no other care but to thin them where they grow too close, and keep them clean from weeds; and if they should grow tall, they must be supported, otherwise the strong winds will break them down; but the 68th sort spreads its branches upon the ground, so will require no support, therefore this only requires to have room, and to be kept clean from weeds.

Others again, as the 2d, 29th, 35th, 54th, 55th, 56th and 57th, being natives of a warmer country, require protection in winter; they are easily propagated by cuttings in the spring and summer months. If these are planted early in the spring, it will be the better way to plant them in pots, which should be plunged

[r] Linn. mant. [s] Hort. kew. [t] Desfontaines.

Digitized by Google

into a very moderate hot-bed; and, if they are ſhaded from the ſun in the heat of the day, and gently refreſhed with water as they may require it, they will have put out good roots in about two months, when they ſhould be inured gradually to the open air, into which they ſhould be removed ſoon after. The cuttings, which are raiſed early in the ſeaſon, will become ſtrong plants before winter, and will be in a better condition to reſiſt the cold than thoſe which are weak.

If the cuttings are planted in ſummer, they will require no artificial heat, ſo that if theſe are planted on a bed of freſh loamy earth, and covered cloſe down with a bell or hand-glaſs, and ſhaded from the ſun in the heat of the day, giving them now and then a little water, they will take root freely; and when they begin to ſhoot, they ſhould have free air admitted to them by raiſing the glaſs on one ſide, and ſo gradually expoſed to the open air. When the plants are well rooted, they ſhould be each tranſplanted into a ſeparate ſmall pot filled with freſh light earth, and placed in a ſhady ſituation till they have taken new root; then they may be removed to a ſheltered ſituation, where they may remain till the approach of froſt, when they muſt be carried into ſhelter, and in winter treated in the ſame manner as other hardy green-houſe plants, which only require protection from froſt, obſerving not to over-water them during the cold weather, but in ſummer, when they are in the open air, they will require it often.

16, 17. Sow the ſeeds in the ſpring, where they are deſigned to remain; keep them clean from weeds, and thin them where they are too cloſe.

26. This, though a native of India, is hardy enough, to live in the open air in England; and the root will abide ſeveral years in a dry ſoil.

[It requires however a little care to be taken of it in ſevere winters. It flowers in great perfection in a large garden pot, but it will ſucceed as well or better in the open border.

This magnificent ſpecies may be increaſed by ſeeds, but theſe being in general ſparingly produced in England, it may be alſo increaſed by parting the roots in the autumn or ſpring[r].]

28. 31. Theſe propagate themſelves in plenty, if the ſeeds are permitted to ſcatter, and only require to be kept clean from weeds.

38 and 52. Theſe rarely or never producing ſeeds in England, are propagated by cuttings, which may be planted any time in ſummer; if theſe are planted in a bed of ſoft loamy earth, and covered cloſe with a bell or hand-glaſs, obſerving to ſhade them from the ſun, and refreſh them with water as they may require it, they will take root very freely, then they muſt be inured to the open air; after they have put out good roots, they ſhould be carefully taken up, and each planted in a ſeparate ſmall pot filled with light freſh earth, placing them in the ſhade till they have taken new root; then they may be placed among other hardy green-houſe plants in a ſheltered ſituation till october, when they ſhould be removed into ſhelter before hard froſt comes on; but as they only require protection from hard froſt, they ſhould have as much free air as poſſible in mild weather.

Mexican Sage muſt have a dry ſituation in winter, for the young ſhoots are very apt to grow mouldy in a damp air.

[41. This charming ſpecies of Sage is now very generally cultivated near London, as a green-houſe plant. It is eaſily propagated by cuttings. In the winter it requires to be placed in a warm dry green-houſe, and to be ſparingly watered, being tender and apt to go off[s].]

48. Sow the ſeeds in the ſpring on an open ſpot of ground; keep the plants clean from weeds, and let them not be nearer than two feet, for they grow very large, and will laſt ſeveral years.

50. This may not only be propagated by ſeeds, but by parting the roots in autumn, and will continue ſeveral years.

[r] Curtis. [s] Idem.

61. Common Clary is propagated by ſeeds, which ſhould be ſown in the ſpring, and when the plants are fit to remove, they ſhould be either tranſplanted into beds, or if a large quantity is required, they may be planted in an open ſpot of ground in rows two feet aſunder, and one foot diſtance in the rows. After the plants have taken root, they will require no farther care but to keep them clean from weeds. The winter and ſpring following the leaves, which are the only part uſed, will be in perfection, and in the ſummer they will run up to flower, and after they have ripened their ſeeds decay, ſo that there ſhould be annually young plants raiſed for uſe. It will thrive upon almoſt any ſoil that is not very wet, for in moiſt ground the plants frequently rot in winter.

The other ſpecies of Salvia, commonly known under the name of Sclarea or Clary, may be propagated and treated in the ſame way; as ſylveſtris, n. 19. nemoroſa, n. 20. ſyriaca, n. 21. hæmatodes, n. 23. pratenſis, n. 24. glutinoſa, n. 50. ceratophylla, n. 63. Æthiopis, n. 64. patula, n. 79. Glutinoſa and ſome others may be increaſed by parting the roots. Moſt of them do beſt in a warm dry ſoil; where ſome will endure ſeveral years.

66. Sow the ſeeds in the beginning of april in a dry or rubbiſhy ſoil, where the plants will live through the winter in the open air, and the ſecond year will produce flowers and ſeeds.

SALVIFOLIA. See *Celtis*.

SALVINIA. (*So named by Micheli, in honour of Antonio Maria Salvini, a nobleman of Florence.*)

Lin. gen. Schreb. n. 1617. *Mich. gen.* 58. *Guettard in act. gall.* 1762. *p.* 549. *t.* 29. *Juſſ.* 16.

Claſſ. 24. 1. Cryptogamia Miſcellaneæ.

GENERIC CHARACTER.

* *Male* Flowers four to nine, among whorled roots, heaped into a little ball.

CAL. ſubglobular, pubeſcent, one-celled, conſiſting of a double membrane, the inner thinner, ten or twelve ribs between them; gaping?

COR. none, unleſs it be the inner membrane of the calyx.

STAM. An upright pillar, placed on the baſe of the calyx, the whole length of it, and putting out from the top from two to three hundred capillary *filaments*. *Anthers* globular, one-celled.

* *Female*, in the middle of the ball, ſolitary.

CAL. and COR. as in the Males.

PIST. *Germs* about fifteen, obliquely ovate, blunt, rugged with dots, each on diſtinct pedicels, faſtened to the bottom of the calyx. *Style* none. *Stigma* a dot on the top of the germ?

PER. none.

SEEDS as many as there are germs, and of the ſame form.

OBS. *The male and female flowers may be diſtinguiſhed in the dry plant before the calyxes open, by the ſize of the protuberant grains.*

For the ſpecies, ſee MARSILEA.

SAMARA.

Rapanea guianensis. *Aubl. guian.* 1. 121. *t.* 46. *Swartz obs.* 51.
Flowers pentandrous, leaves obovate.

DESCRIPTIONS, &c.

1. Branches purplish, even. Leaves alternate, petioled, lanceolate-elliptic, quite entire, even on both sides. Corymbs lateral, axillary, scarcely longer than the petioles. Flowers copious, yellow.—It differs from Cornus not only in having a superior germ, but the filaments opposite to, not alternate with the petals. The leaves also are alternate, whereas in Cornus they are opposite. It is a shrub, and native of the East Indies [t].

2. This is a tree, with a trunk from twenty to thirty feet in height, and upright branches. Branchlets alternate, sometimes four-cornered, even. Leaves alternate, scattered, quite entire, somewhat rigid, nerved and veined, very smooth, membranaceous, dark-green; on short petioles. Flowers lateral and axillary, small, whitish. Balls of flowers scattered, approximating. Calyx four-leaved, or four-parted to the base: leaflets ovate, acute, keeled, scarcely half a line in length, a little connate at bottom. Petals four, slightly connected at the base, oblong, sharpish, spreading, three times as long as the calyx. Filaments very short, inserted into the base of the petals. Anthers oblong, spreading, pressed close to the segments of the corolla, biggish. Germ superior, globular. Style very short. Stigma large, ovate. Berry ? globular, the size of a pepper-corn, one-celled. Some trees of this species have male flowers only. S. læta has smaller thinner leaves and blunt; flowers clustered, not conglomerate, but subumbelled, on pedicels a line and half in length; and the corollas more coloured.

Native of Jamaica, in the southern parts, in woods on the mountains [u].

3. Native of the Cape of Good Hope. Introduced about 1770. It flowers from november to february [x]. Distinct from the two preceding, and agreeing with the next species in having five stamens to the flowers.

4. This is a shrub, with the trunk five feet high, branched at top. Leaves alternate, petioled, thick, smooth, quite entire. Flowers in bundles, subsessile, scattered over the bark of the branches and branchlets. Corolla white. The unripe germ exhibits five or six seeds, but one only ripens. Berry violet-coloured. It flowers and fruits in december.

Native of Cayenne and Guiana on the margins of meadows or savannas [y].

DESCRIPTIONS, *&c.*

1. [Root creeping. Stems herbaceous, three feet high, upright, roundiſh, grooved, leafy, ſomewhat enlarged at the joints, purpliſh, branched above; the branches oppoſite and upright. Leaves oppoſite, unequally pinnate, dark green, ſmoothiſh: leaflets four to ſix pairs, ovate-lanceolate, veined, acute, ſerrate, unequal and generally glandular at the baſe, ſmooth above, downy with a ſlight roughneſs underneath, and whiter; the lowermoſt often lobed. Stipules large, leafy, ſerrate, ſometimes accompanying a pair of leaflets as well as the whole leaf. Cyme terminating, in three principal branches, and thoſe dividing into many others, hairy and many-flowered. All the flowers pedicelled. Calyx ſmall, purple. Corolla of a dull blood-red. Filaments thick, upright, white, with red anthers, having the lobes ſo diſtant, that Dr. Withering conſiders them as diſtinct, and the flower therefore as having ten anthers. Berries globular, purpliſh black, with three, ſometimes four ſeeds[a].

The dwarf Elder, formerly called Wall-wort or rather Wale-wort, and Danewort, from a notion of its having ſprung from the blood of the Danes; differs from the common Elder in being herbaceous, in having a creeping root, and narrower leaflets more numerous, and ſometimes lobed[b].

Mr. Woodward remarks, that the ſtems are very brittle: and Dr. Withering, that the calyx has ſometimes ſix ſegments, and that the diviſions of the corolla are pointed, white above and purple beneath.

Mr. Curtis ſpeaks of the ſtem as ſix feet in height; I have never ſeen it near ſo high.] Mr. Miller gives it from three to five feet, in proportion to the goodneſs of the ground: he diſtinguiſhes this from the common Elder, by the number and ſhape of the leaflets: that ſeldom has more than five, broader and much ſhorter than in this, and pretty deeply ſerrate; whereas the dwarf Elder has nine, eleven or even thirteen leaflets, long, narrow, and very ſlightly indented. The flowers are ſmaller in this, and ſpotted with red. The berries alſo are ſmaller.

[Native of many parts of Europe, in waſte ground, balks of corn fields, by hedges and way ſides, flowering in july. In the midland counties of England it is not uncommon; in Cambridgeſhire rather frequent. About London not ſo, Mr. Curtis having found it only about Lambeth-marſh, and in a lane leading to Upton, Eſſex, by the garden wall of the late Dr. Fothergill. Dr. Milne however ſays, that he found it abundantly at Ratley or Ratcliffe, ſix miles from Barnet, at Ewell in Surry, between Eaſt and Weſt Tilbury, a little beyond Oſpringe and in Uxbridge church-yard. Alſo near Farnham, St. Edmund's Bury, Harwich, and St. Clement's church-yard, Ipſwich. Blackſtone obſerved it on Uxbridge moor. Warner, in the lane between Sewardſtone, commonly called Sufan and Waltham-Abbey. Dr. Smith, at Honingham in Norfolk. Dr. Sibthorp, in the parks behind Wadham College, and near Eynſham. Dr. Withering, at the foot of Tamworth Caſtle-hill. Mr. Pitt, at Tutbury Caſtle. Mr. Atkinſon, near Dalton, Lancaſhire. Gerarde remarked it at Kilburn Abbey on the road to Edgware, near Dartford in Kent, at old Brentford town's end next London, and many other places. The berries ripen late in the autumn; but, like the fruit of many other creeping plants, ſeldom perfect their ſeeds.

The whole plant has a faint diſagreeable ſmell, reſembling that of common Elder, but ſtronger and more unpleaſant. It has the ſame properties with common Elder, but in ſome reſpects more violent. A dram and half of the root is a ſtrong purge. A rob of the berries, though actively cathartic, may be uſed with tolerable ſafety as far as an ounce in a doſe; but it has the inconveniences of Senna, and is in no reſpect to be preferred to that drug. No cattle will eat this plant. Moles will not come where the leaves of this or the common Elder are laid. They alſo drive away mice from granaries, and the Sileſians ſtrew them where their pigs lie, under a perſuaſion that they prevent ſome of the diſeaſes to which ſwine are liable[c].]

β. Mr. Miller makes the cut-leaved dwarf Elder a diſtinct ſpecies. He ſays that the roots do not creep ſo much; that the ſtems do not riſe ſo high; that the leaves have ſeldom more than ſeven leaflets, and towards the top only five, longer and narrower than in the common dwarf Elder, deeply cut on their edges, and ending with winged acute points.

2. This riſes to the height of twenty feet in North America, but in England it is ſeldom much more than half that height. The leaves have generally ſeven or nine leaflets, which are longer and narrower than thoſe of the common Elder: the berries are ſmaller, of the ſame black colour, but not ſo full of juice; nor have the leaves ſo ſtrong a ſcent.

[It is a middle ſpecies between Ebulus and nigra, having the habit of the latter, but pinnate leaves, with the lower leaflets ternate, and all more of an ovate form. It is ſhrubby, but commonly periſhes above ground in winter. The cymes are of the ſame ſtructure as in nigra; and the ſtipules are filiform and truncate, as in that, not expanded into leaflets, as in Ebulus. The berries are reddiſh, and ſaid to be eatable[e].

In the Mantiſſa Linneus remarks, that it is perhaps a variety, with the leaves ſimply pinnate; the berries globular and red, the ſize of Coriander ſeed.

The ſtem, ſays Willdenow, in our gardens, is perennial; the leaves bipinnate, ſeldom ſimply pinnate; the flowers as in S. nigra, but ſmaller and ſmelling ſtrong; the berries ſmall, dark red and ſweet.

Native of North America. Cultivated in 1768, by Mr. Miller. It flowers from june to auguſt[d].

3. The common Elder grows to a bulky tree, twelve or ſixteen feet in height, much branched, and covered with a ſmooth gray bark when young, which becomes rough on the trunk and older branches. Wood hard, tough, yellow, poliſhing almoſt as well as the box-tree; the younger branches containing a very large proportion of medullary matter or pith. Leaves oppoſite, unequally pinnate: leaflets commonly five, ſmooth, nearly equal at the baſe, with very ſmall or no ſtipules. Cymes terminating, dividing into five principal branches, and many ſmall ones. Flowers cream-coloured, with a ſweet but faint ſmell, eſpecially when dried. Stamens divaricating; anthers yellow, ſagittate, ſingle. Berries globular, blackiſh purple, mawkiſhly ſweet[e]: the juice watery and red. There are three little threads in the axis of the berry, inſerted into the apex of the ſeeds; which are oblong, narrowing upwards, cartilaginous, ſhagrined with very ſmall wrinkles, flatted a little, ſlightly convex on one ſide and ſomewhat angular on the other[f].

Native of Britain and many other parts of Europe; alſo of Africa, Japan, &c. With us it is abundant in damp hedges and woods; flowering in may and june.

The whole plant has a narcotic ſmell, and it is not prudent to ſleep under its ſhade. The wood is commonly made into ſkewers for butchers, tops for angling rods, and needles for weaving nets; it is not bad to

turn

Digitized by Google

turn in the lathe. The pith being exceedingly light, is cut into balls, uſed in electrical experiments.

This tree is as it were a whole magazine of phyſic to ruſtic practitioners, nor is it quite neglected by more regular ones. An ointment is made of the green inner bark, which is alſo a ſtrong purgative: in ſmaller doſes it is diuretic, and has done eminent ſervice in obſtinate glandular obſtructions and in dropſies. Sydenham, who recommends it as an effectual hydragogue, directs three handfuls of it to be boiled in a quart of milk and water, till only a pint remains, of which one half is to be taken night and morning, and repeated ſeveral days. Boerhaave gave its expreſſed juice in doſes from a dram to half an ounce. It uſually operates both upwards and downwards. If ſheep that have the rot can get at the bark and young ſhoots, they will ſoon cure themſelves. It is an ingredient in the black dye.—The leaves are alſo purgative, but more nauſeous than the bark. They are an ingredient in ſeveral cooling ointments. If turneps, cabbages, fruit-trees or corn be whipped with the green leaves and branches of Elder, or if a gate ſtuck with the branches be drawn over the crops, it is ſaid that inſects will not attack them. An infuſion of the leaves is uſeful for curious gardeners to ſprinkle over the buds of ſuch flowers as they wiſh to preſerve from minute caterpillars, for few inſects can bear the Elder. It has however its *Phalæna* and *Aphis*; the latter of which, according to Evelyn, is exceedingly troubleſome, and gathers a fiery redneſs where it attacks. Not only inſects abhor the Elder, but the leaves laid into the ſubterraneous paths of the Mole are ſaid to drive it away. The flowers are reported to be fatal to turkies, and the berries to poultry in general.—A decoction of the flowers, taken internally, is ſaid to promote expectoration in pleuriſies: freſh gathered they are gently laxative and aperient; when dry, they are ſaid to promote chiefly the cuticular excretion, and to be particularly ſerviceable in eryſipetalous and eruptive diſorders: externally they are uſed in fomentations, to eaſe pain and abate inflammation; in the London Pharmacopœia they are directed in form of an ointment. Many perſons uſe them to give a flavour to vinegar.—The berries are boiled into a rob, which is really uſeful in ſore throats and catarrhs, and acts as a gentle laxative in febrile diſorders. The officinal preparation of theſe berries is the *ſuccus baccæ ſambuci ſpiſſatus* of the London Pharmacopœia. The juice of the berries is employed to give a red colour to raiſin or ſugar wines [g]; and ſome country houſewifes make a wine with this juice chiefly or only, which they eſteem very wholeſome, but many people think it nauſeous.

Linneus ſays, that ſheep eat the Elder, but that horſes, cows and goats refuſe it; others report that cows are fond of it [h].] Mr. Miller remarks, that the leaves and ſtalks are ſo nauſeous, that few animals will browſe upon it: and that he has often ſeen the trees growing in parks, where there has been a variety of animals, which were untouched, when almoſt all the other trees within reach were cropped by the cattle.

β, γ. The varieties of the common Elder, are thoſe with white or green berries, and variegated leaves. The latter is undoubtedly a variety; and thoſe with white and green berries are the ſame: but it may be doubted whether this is not a diſtinct ſpecies, the leaflets being much ſmaller, and very ſlightly ſerrate, whereas thoſe of the common ſort are deeply ſerrate; they are alſo ſmoother, and of a lighter green.

δ. Parſley-leaved Elder is a diſtinct ſpecies, in the opinion of Mr. Miller: the leaflets being narrower, and cut into ſeveral ſegments, which are again deeply indented on their edges regularly, in form of winged leaves. The ſtalks are much ſmaller, and the ſhoots are ſhort; the leaves have not ſo ſtrong an odour, and the berries are a little ſmaller.

[Retzius, in his third faſciculus, believed this to be a diſtinct ſpecies, but in his ſixth he abandoned this opinion, having found that the ſeeds uniformly produce only the common Elder.

3. Stem ſhrubby, with the branches empty, ſmooth, oppoſite, round, patulous. Leaves oppoſite, unequally pinnate; leaflets in three, five or ſeven pairs, ovate, acute, often acuminate, ſerrate with the margin cartilaginous and white, ſmooth, an inch or a little more in length. Common petiole round, ſmooth: partial petioles half an inch long. Flowers terminating, panicle-cymed. Cyme ſuperdecompound, trichotomous, naked without bractes, ſmooth, ſpreading. Corollas white. Filaments ſhorter than the corolla. Germ ſuperior. Style filiform, ſhorter than the ſtamens. Stigma capitate, white.—Native of Japan [i].]

5. This ſends up many ſhrubby ſtalks from the root, riſing ten or twelve feet high, and dividing into many branches, which are covered with a brown bark. Leaves oppoſite; the lower generally compoſed of two pairs of leaflets, terminated by an odd one, ſhorter and broader than thoſe of the common Elder, and deeply ſerrate; the upper have frequently but three leaflets; they are of a pale green colour and pretty ſmooth. Flowers of an herbaceous white colour, appearing in april, and ſometimes ſucceeded by berries, which are red when ripe.

[Native of Germany, Switzerland, Italy and Siberia. Cultivated in 1596, by Gerarde [k].

The leaves are eaten by the red deer, and the berries by partridges, moor-game, and other birds of that order [l].]

PROPAGATION AND CULTURE.

1. Dwarf Elder propagates itſelf faſt enough wherever it is once planted, by its creeping roots, inſomuch that it is very difficult to keep it within bounds.

2. Canadian Elder will put out roots from cuttings almoſt as eaſily as the common ſort; but being liable to injury from ſevere froſts, it ſhould be planted in a ſheltered ſituation.

5. The common, and the red-berried Elder may be eaſily propagated from cuttings, or by ſowing their ſeeds; but the former being the moſt expeditious method, is generally practiſed. The ſeaſon for planting their cuttings is any time from ſeptember to march, in the doing of which, there needs no more care than to thruſt the cuttings about ſix or eight inches into the ground, and they will take root faſt enough, and may afterwards be tranſplanted where they are to remain, which may be upon almoſt any ſoil or ſituation; they are extremely hardy, and if their ſeeds are permitted to fall upon the ground, they will produce plenty of plants the ſucceeding ſummer.

Theſe trees are often planted for making fences, becauſe of their quick growth; but as their bottoms become naked in a few years, they are not ſo proper for that purpoſe; neither would I recommend them to be planted near habitations, becauſe at the ſeaſon when they are in flower, they emit ſuch a ſtrong ſcent, as will occaſion violent pains in the heads of thoſe who abide long near them; beſides the crude parts which are continually perſpired through their leaves, are accounted unwholeſome, though the leaves, bark, and other parts, are greatly eſteemed for many uſes in medicine.

The common Elder will grow in any ſoil or ſituation. It is frequently ſeen in old walls, cloſe to ditches and in very wet places, and even on hollow trees, for wherever the berries are ſcattered by birds, the ſeeds will come up.

DESCRIPTION, *&c.*

[Root perennial, conſiſting of long white fibres, commonly ſimple. The whole herb is ſmooth. Stem from a ſpan to a foot in height, upright, round, leafy, commonly branched a little at top. Leaves alternate, ſubſeſſile except the root-leaves, obovate, obtuſe, perfectly entire, ſhining, having few veins and thoſe diſtant. Racemes terminating, erect, many-flowered: pedicels commonly in pairs, one-flowered, erect, jointed; with one lanceolate bracte at the joint. Flowers ſmall, ſnow-white: calyx bell-ſhaped, ſcarcely half-five-cleft: tube of the corolla cylindrical; border ſpreading, the ſegments blunt, equal, the ſcales lanceolate. Stamens ſhorter than the tube, included. Style very ſhort [m]. Capſule ſmall, ſubglobular, covered at bottom by the calyx, which is faſtened to it, opening at top half way into five parts. Seeds ſmall, angular, very minutely dotted, of a ferruginous-brown colour, inſerted into a biggiſh, central, globular, ſpongy, free, pedicelled receptacle, full of little cavities [n].

This is properly of the genus of *Montia*, and therefore allied to the *Portulaceæ* of Juſſieu, as that celebrated author ſuſpected. *Sheffieldia repens* of Forſter is another ſpecies, according to the report of Mr. Dryander [o].

It is an inhabitant, as Mr. Curtis remarks, of every quarter of the globe, in marſhes, wet meadows, and great ditches. It is not very common in England, but by no means ſo rare as to make it neceſſary to enumerate its places of growth. July is the month of its flowering.

Mr. Miller conſiders it as annual. Linnæus marks it as biennial; others as perennial.

[m] Smith, Curtis. [n] Gærtner. [o] Smith.

β. The African plant differs in having the ſtem firmer and more branched; but it ſcarcely poſſeſſes ſufficient marks to render it a diſtinct ſpecies [p].]

PROPAGATION AND CULTURE.

If the ſeeds be ſown ſoon after they are ripe on a moiſt ſpot of ground, they will come up readily and require only to be kept clean from weeds.

DESCRIPTIONS, *&c.*

1. Browne calls this ſhrubby Samyda with waxen rudiments, or the larger Clovenberry Buſh. It is frequent, with his two other ſpecies, in Jamaica, growing commonly in the low lands. It ſhoots ſometimes to the height of ſeven or eight feet. The leaves are ſhining and very ſlightly crenate; rudiments or ſegments of the nectary ſoft, red; flowers in ſlender axillary racemes.

2. Branches ſmooth, round, ſcarred with the fallen leaves, yellowiſh. Leaves large, commonly half a foot or more, indiſtinctly crenulate at the edge, ſmooth on both ſides, except that at the axils of the veins and along the midrib they are villoſe. Flowers ſmall, in a peduncled ſubterminating corymb. Calyx bell-ſhaped, with the border five-cleft and revolute. Nectary bell-ſhaped bearing eight very minute awl-ſhaped filaments. Anthers brown. Germ ovate. Style awl-ſhaped. Stigma hairy.—Native of the Eaſt Indies [q].

3. The ſtem ſeems to be ſhrubby. Branches woody, round. Leaves alternate, ovate, ſubſerrate, one-nerved with the nerve branched, tomentoſe beneath. Stipules none, except they were fallen off, or confounded with the axillary ſcalelets. Flowers ſmall, each on its own ſhort peduncle, all ſpringing from a ſcaly axillary globule, at firſt cloſed, afterwards open. Calyx very deeply divided into four whitiſh ovate ſegments. Inſtead of filaments a whitiſh pitcher-ſhaped body, ſurrounding the germ (as in Swietenia and Porteſia) ſupports at its top eight ovate ſeſſile anthers. Germ ovate, gradually narrowing towards the top; ſtigma globular. Deſcribed from a dry ſpecimen.—Native of the Weſt Indies [r].

4. Shrub a fathom high. Leaves alternate, ſpreading, rounded and oblique at the baſe, having a ſhort point at the end, nerved and veined, the nerves beneath ferruginous. Petioles round, ſhort, villoſe. Peduncles axillary, ſolitary, riſing, very ſhort, one-flowered. Flowers biggiſh, white. Certainly different from *pubeſcens*.

Native of Jamaica, in the mountains; flowering in ſpring.

5. A ſmall tree, with a trunk ten or twelve feet high, ſmooth, unarmed. Leaves alternate, ſpreading horizontally, nerved and veined, ſmooth on both ſides, ſhining above, bright green, with pores ſo ſmall as to be ſcarcely viſible. Petioles ſhortiſh. Peduncles in general ſhorter than the petioles and thicker, axillary, ſolitary, one-flowered. Flowers biggiſh, white. Two ſmall acute ſtipules at the baſe of the peduncles. Not to be confounded with *S. nitida*, which has cordate leaves, and other differences. Nor does *Caſearia nitida* of Jacquin agree with this; for it has its nectaries alternate with the ſtamens, and therefore differs from all the ſpecies of Samyda.

6. A ſmall tree. Leaves petioled, ſcattered, alternate, commonly terminating. Stipules intermixed with the petioles, lanceolate, blunt, ſmall, membranaceous. Flowers ſubſeſſile among the leaves at the ends of the branchlets, biggiſh, pale. Quite diſtinct from the other ſpecies, and intermediate between the *Samydas* and *Caſearias*, on account of the calyx being five-leaved, which in them is one-leafed.

Native of Hiſpaniola, where it flowers in december and january [s].

7. This is an obſcure plant, native of America.

8. Shrub three or four feet high, with round ſomewhat villoſe branchlets. Leaves alternate, bifarious, on very ſhort petioles, lanceolate, acute, ſomewhat villoſe on both ſides and at the edges. Peduncles axillary, ſolitary, one-flowered, very ſhort. Bractes to theſe two, ſubulate, ſmall, brown. Flowers without ſmell. Calyx thick, externally villoſe, dirty yellowiſh green, white within. Anthers browniſh. Germ villoſe. Stigma green. Nectary and Style white. Fruit reddiſh yellow. Seeds pale.—Native of America [t].

9. Native of New Caledonia [u].]

PROPAGATION AND CULTURE.

Theſe plants are propagated by ſeeds procured from the countries where they naturally grow. Sow them upon a hot-bed in the ſpring; and when the plants come up ſet them in ſmall pots filled with good kitchen garden earth, plunge them into a hot-bed of tanner's bark, and treat them in the ſame way as other tender plants from the ſame countries. Keep them in the bark-bed till they have acquired ſtrength, and then they may be expoſed in ſummer, but in winter they require a good green-houſe.

Hantol. *Raii ſuppl. app.* 54. 9. *Camelli ic.* 136.

DESCRIPTION, *&c.*

This is a tree with an aſh-coloured bark, and the wood red in the middle. Leaves alternate, on long petioles, ternate. Leaflets petioled, roundiſh-ovate, acuminate, veined, quite entire, ſmooth above, ferruginous-tomentoſe beneath. Petioles tomentoſe. Panicle narrow, axillary, longer than the petiole, naked. It is very nearly allied to Trichilia nervoſa, but ſeems to differ, in not having the leaves veinleſs on the upper ſurface, and in the panicle being naked, not having a lanceolate leaflet to each branch as the Trichilia has.

Native of the Philippine and Molucca iſlands [x]. The fruit is acid. It is called *Hantol* in the Philippine iſlands [y].

SANDWORT. See *Arenaria*.]

DESCRIPTION, *&c.*

[Root tuberous, thick, fleſhy, not unlike that of Tormentilla, placed tranſverſely, with ſeveral ſlender fibres deſcending from it; of a reddiſh ſaffron colour, and yielding a juice of the ſame hue, which gave occaſion to Morinus, and after him Dillenius and others, to give it the name of Sanguinaria; this juice is bitter and acrid, and it flows alſo from the leaves and foot-ſtalks when cut. In the ſpring the root puts forth ſlender round ſmooth ſtems, paliſh green or browniſh tinged with purple, each terminated by a little conical head, which expands into a white flower of eight petals, at firſt concave, then flat, and finally rolled back ſo as to be convex, marked with ſlender ſtreaks. Filaments white with ſaffron-coloured anthers. Germ glaucous. Capſule yellowiſh when ripening, but of a purpliſh glaucous colour when quite dry. Seeds ſhining, yellowiſh and poliſhed like thoſe of Millet. When the flowers are about expanding, a ſingle leaf comes out upon each flower-ſtalk, at firſt ſmall, compreſſed, and protecting the flower with its foot-ſtalk; but afterwards becoming larger, and unfolding into lobes, like thoſe of the Fig, which are thickiſh, ſmooth, internally of a deep glaucous green, externally of a whitiſh glaucous colour, with frequent veins, moſt conſpicuous on the outſide; on petioles which are flat and ſlightly grooved on the inſide, and convex on the outſide. Three or four flower ſtems ariſe from each root, and are ſurrounded at the baſe by oblong, membranaceous, tender, ſtriated ſcales. The root, leaves and flowers have no ſmell[y].

Linneus remarks, that the radical leaf very tenderly embraces and cheriſhes the infant flower, after the manner of Oſmunda Lunaria. There is only a ſingle cowled leaf, and a one-flowered ſcape, from each bivalve bud of the root. The anthers in Linneus's ſpecimen had ſcarcely any pollen in the anthers; he therefore ſuſpects that the plant may be dioecous, but there does not ſeem to be any ground for that ſuſpicion. It has a fulvous milk, like Celandine[z]. With this juice the Indians are ſaid to paint themſelves.

Though the Sanguinaria cannot be conſidered as a ſhowy plant, yet it has few equals in point of delicacy and ſingularity: there is ſomething in it to admire from the time that its leaves emerge from the ground and emboſom the infant bloſſom, to their full expanſion and the ripening of the ſeed-veſſels.

The woods of Canada and other parts of North America produce this plant in abundance. With us it flowers in the beginning of april: its bloſſoms are fugacious, and fully expand only in fine warm weather.

It appears from Moriſon, that it was cultivated in this country in 1680, by Mr. William Walker, in his ſuburban garden, in St. James's ſtreet, not far from St. James's palace.

[y] Dillenius. [z] Lin. ſyſt.

Dillenius has figured three varieties; a large one, a ſmall one, and a third in which the petals are multiplied, but which can ſcarcely be called double[a].]

PROPAGATION AND CULTURE.

This plant is hardy enough to live in the open air in England, but it ſhould be planted in a looſe ſoil and a ſheltered ſituation, not too much expoſed to the ſun. It is propagated by the roots, which may be taken up and parted every other year; the beſt time for doing of this is in ſeptember, that the roots may have time to ſend out fibres before the hard froſt ſets in. The flowers of this plant appear in april, and when they decay, the green leaves come out, which will continue till midſummer; then they decay, and the roots remain unactive till the following autumn; ſo that unleſs the roots are marked, it will be pretty difficult to find them after their leaves decay, for being of a dirty brown colour on the outſide, they are not eaſily diſtinguiſhed from the earth.

This plant is very proper to mix with the Dog's-tooth Violet, Spring Cyclamen, Perſian Iris, Bulbocodium, Siſyrinchium, and ſome other low growing bulbous and tuberous-rooted flowers, which require the ſame culture, where theſe will add to the variety when they are in beauty; for when the roots are ſtrong and grow in a good ſoil, they will produce a great number of flowers upon each root; the roots may be planted about four or five inches aſunder every way.

A ſoil having a mixture of bog earth or rotten leaves in it, ſuits this plant beſt.

DESCRIPTIONS, *&c.*

1. [This is a hardy plant, from eighteen inches to two feet and a half in height. Stem upright, almoſt naked, branching towards the top. Leaves unequally pinnate, conſiſting of four, five or ſix pairs of leaflets, which are ovate-oblong, cordate, acutely crenate, ſmooth, near two inches long, and an inch broad at the baſe. Spikes thick, blunt, of a dark blood-red, the upper flowers expanding firſt, and being commonly without ſtamens, or only an imperfect one. Segments of the corolla mulberry-coloured, hairy on the outſide at the baſe; tube white, fleſhy, incloſing the germ; a glandular ring cloſely embracing, but not adhering to the ſtyle: the ſegments, when old, adhere ſo ſlightly at the baſe, that the corolla might almoſt be conſidered as four-petalled. Beſides the ſmooth coat formed by the permanent baſe or tube of the corolla, there is an ovate ſeed-veſſel, including one ſeed [b].

It differs from the next ſpecies, in having ovate, not cylindrical ſpikes; and ſmooth calyxes, not ciliate at the edge [c].

Native of many parts of Europe, Linneus ſays in drier meadows, with us in moiſt meadows, particularly in a chalky or limeſtone ſoil, principally in the northern parts of the iſland. Mr. Woodward informs us, that he has not found it farther to the ſouth-eaſt than Ripton in Huntingdonſhire. It is common in lime-ſtone paſtures in the north, and not uncommon in marly ſoils about Stafford. In Cambridgeſhire, at King's-hedges, Whitwell, Ditton, Shelford, Long Stanton, Cottenham. In Bedfordſhire, at Bromham, Fenlake and Cow meadows. In Oxfordſhire, at Iſley, Cowley and Binſey. Scotland, in low moiſt meadows near Dumfries, &c. but not common.

Old Gerarde ſays: "my ſelfe have founde it growing upon the ſide of a cawſey which croſſeth the one halfe of a fielde, whereof the one part is earable grounde, and the other part medowe, lying betweene Paddington and Lyſſon greene, neere unto London, upon the high way." Parkinſon alſo points it out as growing not only there, but by Pancras church. It is not noticed in Curtis's Flora Londinenſis, or by Dr. Milne, in his indigenous botany. It is found about Grantham in Lincolnſhire: Beſton and Lenton in Nottinghamſhire; and Parkinſon ſays it is common in Huntingdon and Northampton ſhires. It flowers in june and july.

This plant is too hard and ſticky for cattle; nor has it any of the Cucumber ſmell, which is found in the Poterium or leſſer Burnet. It is certainly a defect in the Linnean ſyſtem that two plants ſo ſimilar in habit, ſhould be ſo diſtant from each other.]

β. The Italian Burnet riſes with ſtiff upright ſtalks more than three feet high, branching out towards the top; each branch terminated by a cylindrical ſpike of brown flowers, ſmaller than thoſe of the common ſort. Leaves on very ſtrong foot-ſtalks, much longer than in that: they have ſeven or eight pairs of ſtiff leaflets, oblong-heart-ſhaped, deeply ſerrate, of a lucid green on the upper ſide, but pale on the under, on pretty long pedicels, at the baſe of which come out two ſmall roundiſh leaves or ears, which are deeply indented.

γ. The leaves of the Spaniſh Burnet are ſmaller, having but four pairs of leaflets, bluntly ſerrate, pale green above and hoary beneath, on very ſhort foot-ſtalks. The ſtalks riſe about two feet high, and branch pretty much towards the top: the branches are terminated by round heads or ſpikes of reddiſh flowers.

[Mr. Miller conſiders theſe as ſpecifically diſtinct from our great Burnet.

2. The ſpikes of flowers are cylindrical and longer; the ſtamens alſo are longer than in S. officinalis [d].

According to Moriſon, the leaves are larger, longer and more ſerrate.

Native of Canada. Introduced in 1785, by Mr. John Bell. It flowers from july to ſeptember [e].]

3. This has leaves like thoſe of the common ſort, but a little ſtiffer, compoſed of four or five pairs of leaflets; thoſe on the lower part of the midrib ſtand alternate, but the two upper pairs are oppoſite; they are of a light green colour, and deeply ſerrate. The ſtalks riſe three feet high, dividing towards the top into ſmall branches, which ſtand erect, and are terminated by long ſpikes of flowers of an herbaceous white colour, each upon a ſhort foot-ſtalk.

There is another with long ſpikes of red flowers, of a higher growth, with thicker ſpikes, and broader leaflets whiter underneath.

[Moriſon remarks, that this red-ſpiked American Burnet has the ſpikes three or four inches long; whereas in the herbaceous-ſpiked they are only two or three. He ſays that the lower flowers open firſt, and that they are of a yellowiſh green colour.

Native of North America and Siberia.—It appears from Parkinſon that it was cultivated here in 1640. It flowers from june to ſeptember [f].]

PROPAGATION AND CULTURE.

The Burnets are very hardy perennial plants, and will thrive in almoſt any ſoil or ſituation. They may be propagated either by ſeeds or parting of the roots; if they are propagated by ſeeds, they ſhould be ſown in in the autumn, for when they are ſown in the ſpring, they ſeldom grow the ſame year: when the plants come up, they muſt be kept clean from weeds till they are ſtrong enough to tranſplant, when they may be planted in a ſhady border, at about ſix inches diſtance each way, obſerving to water them till they have taken new root, after which they will require no other care but to keep them clean from weeds till autumn, when they may be tranſplanted to the place where they are to remain; the following ſummer they will produce flowers and ſeeds, but their roots will abide many years.

If the roots are parted, it ſhould be done in autumn, that they may get good root before the dry weather comes on in the ſpring.

DESCRIPTIONS, *&c.*

1. Root perennial, with long branched fleſhy fibres. Stem from twelve to eighteen inches high, upright, round, grooved, almoſt naked, little branched, ſmooth. Leaves petioled, ſmooth, deeply ſeven-lobed or five-lobed, deep green above, paler green and ſhining underneath; the lobes wedge-ſhaped, trifid, cut and ſerrate, with briſtles at the end of the ſerratures. Univerſal umbel unequal, with the rays often branched. Univerſal involucres two-leaved, leafy, pinnatifid: partial many-leaved; the leaflets lanceolate, acute, entire. Flowers ſeſſile, heaped, white or reddiſh: the petals all nearly equal, entire. The central ones are male, having no ſtyle, but in its place a concave glandular nectary, ſimilar to what crowns the germ in the fertile florets. The female florets have elongated, acute calycine teeth, but no petals, according to Scopoli; Mr. Wood however informs us that they are only deciduous [g].

Native of Europe, in woods and thickets, flowering in may.

This plant was much celebrated formerly as a vulnerary. It diſcovers to the taſte, ſays Lewis, ſome bitteriſhneſs and roughneſs, followed by an impreſſion of acrimony which affects chiefly the throat: in the freſh leaves the taſte is very weak, in the dry leaves conſiderable: in the extract made from them by water or ſpirit, moderately ſtrong.—Sanicle has long been entirely diſcarded as a medicine; and in Dr. Smith's opinion ſeems to partake of that viroſe acrimony which is found in moſt umbelliferous plants growing in a moiſt fat ſoil.

2. This is ſo ſimilar in ſtructure to the preceding, that there is ſcarcely any difference except that it is frequently ten times as large in all its parts.

Native of Virginia [h]. Found alſo at the Cape of Good Hope and in Japan by Thunberg. Nothing therefore can be more unfortunate than the trivial name adopted by Linneus from Tournefort. Names indeed taken from their native place are generally of the worſt ſort.

3. Root perennial. The whole plant ſmooth. Stem annual, erect, about two feet high, the thickneſs of a quill, with alternate branches, trichotomous at top. Root-leaves on long petioles, ternate, acutely ſerrate, acute; leaflets rhombed, ſubſeſſile, the middle one three-lobed at top, the ſide ones two-parted into ſubtrilobate lobes like the middle one. Lower ſtem-leaves alternate, like the root-leaves, but ſharper and ſmaller. Upper ſtem-leaves and branch-leaves at the diviſions oppoſite, almoſt ſeſſile, ternate, ſerrate, acute, but ſcarcely lobed. Umbels peduncled, ſimple, few-flowered. Male flowers on ſhort pedicels. Females ſeſſile. Leaves of the involucre few ovate and acute, ſometimes lobed. Leaflets of the perianth lanceolate, acute, concave, erect, green, the length of the corolla. Petals whitiſh, acute, bent in, erect. Germ hiſpid. Fruit roundiſh-compreſſed, echinate, brown, ſmall [i]. A ſort of two-celled capſule, not bipartile or ſeparating from the ſeed. One of the ſeeds is commonly abortive [k].

Native of Virginia and Maryland. Introduced in 1765 by Mr. John Cree. It flowers in june and july [l]. It is not in the Linnean herbarium, and Mr. Dryander ſuſpects it not to differ from the preceding.

PROPAGATION AND CULTURE.

Part the roots, any time from ſeptember to march; but the beſt time is in autumn. In a moiſt ſoil, and a ſhady ſituation they will thrive exceedingly.

DESCRIPTION, *&c.*

This tree has the appearance of a Myrtle, with ſtiff brachiate branches, every where jointed [m]. In habit

[g] Smith and Withering. [h] Linn. [i] Jacquin. [k] Gærtner. [l] Hort. kew. [m] Linn. mant.

leaves

Digitized by Google

leaves and inflorescence resembling the Privet[m]. Leaves opposite, on short petioles, spreading, lanceolate, entire, waved, smooth, shining, about two inches long, and three quarters of an inch broad. Stipules none. Flowers small, red, in a terminating, compound, small, erect, thyrse-like raceme. Calyx superior, bell-shaped, four-cleft: divisions ovate, expanding, coloured. Corolla none, except the nectary be such. Nectary four-leaved, obcordate, notched, inserted into the mouth of the calyx. Filaments short, hairy, inserted into the calyx alternately with the leaflets of the nectary. Stigma four-lobed. Berry globular, size of a large pea, smooth, juicy, black when ripe.

This valuable tree is a native of many parts of India. In the Circar mountains, where it is wild, it is but of a small size, and the wood of little value. On the Malabar coast it is much larger, and the wood of the best sort.

This wood is the white and yellow Sanders or Sandal wood, Santalum album and flavum of the Materia Medica; both being the produce of the same tree, and not, as Garcias says, of different trees. Most trees in India, when large and old, become coloured towards the centre; that part is always much more hard and durable than the exterior uncoloured part. So it is with the Sandal tree: the centre, when the tree becomes large, acquires a yellow colour, great fragrance and hardness; while the exterior part of the same tree, that covers the coloured part, is less firm, white and without fragrance. It is only the yellow part that is of use; and the larger the tree the more valuable is the wood, it having then acquired a greater degree of fragrance, for which alone it is held in such universal estimation.

Birds eat the berries greedily, by which means it is propagated extensively[n].]

SANTOLINA. (*Dimin. q.* Sanctolina. *Holy Herb; so named on account of its supposed medical qualities.*)

Lin. gen. n. 942. *Reich. n.* 1022. *Schreb. n.* 1278. *Tournef. t.* 260. *Vaill. act. gall.* 1719. *Juss.* 185. *Gærtn.* 165.

Class. 19. 1. Syngenesia Polygamia Æqualis.

Nat. order of *Compositæ Discoideæ. Corymbiferæ*, Juss.

GENERIC CHARACTER.

CAL. *Common* hemispherical, imbricate: *scales* ovate-oblong, acute, pressed close.

COR. *Compound* uniform, longer than the calyx. *Corollets* hermaphrodite, equal, numerous.

Proper one-petalled, funnel-form: *border* five-cleft, revolute.

STAM. *Filaments* five, capillary, very short. *Anther* cylindrical, tubulous.

PIST. *Germ* four-cornered, oblong. *Style* filiform, length of the stamens. *Stigmas* two, oblong, depressed, truncate.

PER. none. *Calyx* unchanged.

SEEDS solitary, oblong, four-cornered. *Down* none.

REC. chaffy, flattish: *Chaffs* concave.

OBS. S. alpina *differs in having no female florets.*

ESSENTIAL CHARACTER.

Cal. imbricate, hemispherical. *Down* none. *Recept.* chaffy.

Peduncles corymbed, leaves oblong blunt crenate densely woolly.

DESCRIPTIONS, &c.

1. Common Lavender-Cotton has a shrubby stalk, dividing into many woody branches; with slender hoary leaves, indented four ways, and having a rank strong odour when handled. The branches divide towards the top into several slender stalks, the lower parts of which have a few small leaves of the same shape as the others, but naked above, and terminated by

[m] Willdenow. [n] Roxburgh.

Digitized by Google

by a ſingle flower, compoſed of ſulphur-coloured fiſtular florets, without any ray. [Receptacle convex, covered on all ſides with oblong blunt keeled chaffs, pubeſcent on the outſide at top. Seeds oblong, acuminate downwards, blunt above, angular, indiſtinctly ſtriated, pale, bald, terminated by a blunt little point[o].]

This plant will riſe near three feet high, in a dry ſoil and ſheltered ſituation. The flowers appear in july. [It was cultivated in 1596, by Gerarde[p]; who ſays it was then very common in the Engliſh gardens.

Native of the South of Europe; as Spain and Italy. Haller is doubtful whether it be a native of Switzerland.

Lavender-Cotton is acrid, bitter and aromatic, and has much the ſame qualities as Southernwood. It is reputed reſolvent, corroborant and diaphoretic. The leaves or flowers in powder may be given in the doſe of a dram as a vermifuge, or twice that quantity in infuſion[q]. As a medicine it is diſuſed among us.]

β. Hoary Lavender-Cotton branches out like the common ſort, but ſeldom grows ſo tall. The branches are divided into a great number of ſtalks, which are ſhort, hoary, and below ſet very cloſely with ſhorter, thicker and whiter leaves. The flowers are much larger, and the brims of the florets are more reflexed; they are alſo of a deeper ſulphur colour. It grows naturally in Spain.

γ. This is of ſtill lower ſtature, ſeldom riſing more than fifteen or ſixteen inches high. The branches ſpread horizontally near the ground, and have ſhorter leaves than either of the former; they are hoary, and finely indented; the ſtalks are ſhort, and are each terminated by a ſingle flower of a bright yellow colour, and larger than thoſe of the common ſort.

δ. The dark-green Lavender-Cotton riſes higher than theſe; the branches are more looſely diſpoſed, and more diffuſed; they are more ſlender, ſmooth, and have very narrow long leaves of a deep green colour, indented only two ways; the ſtalks are ſlender, naked towards the top, and terminated by ſingle flowers of a gold colour. [Mr. Miller conſiders theſe varieties as diſtinct ſpecies.

2. Roſemary-leaved Lavender-Cotton is herbaceous, ſcarcely ſuffruticoſe. Leaves at the edge on both ſides crenulate with tubercles in two rows, but on the flowering-ſtalk linear, toothletted on each ſide at the top. Peduncles long, terminating, one-flowered[r].

According to Willich, the ſcales of the calyx are narrow and acute, the uppermoſt bent back outwards at the tip. The ſeeds are crowned with a ſimple down almoſt as long as the corolla. Receptacle honeycombed, naked.]

Stalks ſhrubby, about three feet high, ſending out long ſlender branches, with ſingle linear leaves about an inch and half long, pale green and entire. The ſtalks are terminated by large, ſingle, globular flowers of a pale ſulphur colour.

[D'Aſſo deſcribes it as a ſuffruticoſe plant, a foot in height, with rod-like one-flowered ſtems naked at top. Leaves linear, acute, fleſhy, with a double row of toothlets on each ſide. Flowers twice as large as in the common ſort. Chaffs concave.—How comes Willich to aſſert that the receptacle is naked?

Native of Spain. Cultivated in 1683, by Mr. James Sutherland. It flowers from july to ſeptember[s].]

β. The branches of this are ſhorter, thicker, and cloſer ſet with leaves; which come out in cluſters, are ſhorter, and blunt. The flower-ſtalks are ſparſedly diſpoſed, and have leaves to their top. The flowers are ſmall and yellow.

[3. Stem hoary, with alternate branches. Leaves alternate, ſeſſile, approximating; the younger ones imbricate, crenulate, blunt, thick, villoſe. Corymbs terminating, compound. Scales of the calyx oblong, blunt, keeled, villoſe. Chaffs of the receptacle oblong, membranaceous at the edge[t].

4. The flowers are without any female florets[u]. It is herbaceous, and has the leaves cut into very fine ſegments, as in *Anthemis* and *Chamæmelum*.

Native of Tuſcany, among ruins of rocks, flowering in june[x].

5. This plant is a palm in height. Stem villoſe, leafy. Leaves like thoſe of Chamomile pubeſcent. Peduncles terminating, longer than the leaves, when fruiting ſtiffiſh.—Native of Spain, Italy[y], and Siberia.]

Miller deſcribes his *chamæmelifolia* as having ſhrubby ſtalks which riſe near three feet high, and divide into many hoary branches, with broader leaves, having the indentures looſer but double; they alſo are hoary, and when bruiſed have an odour like Chamomile; they are placed pretty far aſunder, but quite to the top of the ſtalks; which are divided at the end into two or three footſtalks, each ſuſtaining one pretty large ſulphur-coloured flower.

6. [For the deſcription of this ſpecies ſee Athanaſia maritima.—Linneus, in the firſt edition of his Species Plantarum, made it a *Filago*; in the ſecond an *Athanaſia*; but in his obſervations on this edition, as we are informed by Dr. Smith, he corrected it to *Santolina*. Gærtner, following Tournefort and many old authors, inſiſts that it is a *Gnaphalium*, and that it differs not only from Athanaſia and Filago, but from all the *Diſcoideæ*, in the very unuſual form of the corollets, which are compreſſed and dilated below, ending at the baſe in two nectariferous proceſſes like ſpurs embracing the ſide of the germ. He deſcribes the receptacle as convex or ovate-globular, ſmall, and covered with oblong concave chaffs, externally tomentoſe at the top: the ſeeds as ſmall, oblong, acuminate downwards, compreſſed and bald.

He alſo remarks that Browne (*hiſt. jam.* 315.) very rightly referred *Calea oppoſitifolia* and *Amellus* to the genus *Santolina*; there being no veſtige of a pappus in them, and the whole ſtructure of the flower being very like that of *Santolina*.]

PROPAGATION AND CULTURE.

Theſe are hardy plants, which will thrive in the open air, provided they are planted in a poor dry ſoil, for in ſuch ground the plants being ſtinted, will be better able to reſiſt the cold; and they will have a better appearance than thoſe which are in rich ground, whoſe branches being long and diffuſed, by hard rains or ſtrong winds are diſplaced, and ſometimes broken down; whereas, in poor land, they will grow compact, and the plants will continue much longer.

Theſe plants may be cultivated ſo as to become ornaments to a garden, particularly in ſmall boſquets of evergreen ſhrubs, where, if they are artfully intermixed with other plants of the ſame growth, and placed in the front line, they will make an agreeable variety, eſpecially if care be taken to trim them twice in a ſummer to keep them within bounds, otherwiſe their branches are apt to ſtraggle, and in wet weather to be borne down and diſplaced, which renders them unſightly; but, when they are kept in order, their hoary and different-coloured leaves will have a pretty effect in ſuch plantations.

They may be propagated by planting ſlips or cuttings during the ſpring; they ſhould be put into a border of light freſh earth, and watered and ſhaded in dry weather until they have taken root, after which they will require no farther care, but to keep them clear from weeds till autumn, when they ſhould be carefully taken up, and tranſplanted where they are deſigned to remain; but if the ground is not ready by that time to receive them, it will be proper to let them remain in the border until ſpring; for if they are tranſplanted late in autumn, they are liable to be deſtroyed by cold in winter.

Unarmed, leaves abruptly pinnate, leaflets lanceolate quite entire ſmooth.]

DESCRIPTIONS, *&c.*

1. The firſt ſort grows naturally in the iſlands of the Weſt Indies, where it riſes with a woody ſtalk from twenty to thirty feet high, ſending out many branches towards the top, which are garniſhed with winged leaves, compoſed of three, four, or five pair of ſpear-ſhaped leaflets, which are from three to four inches long, and an inch and a quarter broad in the middle, drawing to a point at both ends. The midrib has a membranaceous or leafy border running on each ſide from one pair of leaflets to the other, which is broadeſt in the middle between the leaflets; they are of a pale green colour, and are pretty ſtiff; the flowers are produced in looſe ſpikes at the end of the branches; they are ſmall and white, ſo make no great appearance. Theſe are ſucceeded by oval berries as large as middling Cherries, ſometimes ſingle, at others two, three, or four are joined together; theſe have a ſapo-naceous ſkin or cover which incloſes a very ſmooth roundiſh nut of the ſame form, and of a ſhining black when ripe. Theſe nuts were formerly brought to England for buttons to waiſtcoats, ſome were tipped with ſilver, and others with different metals; they were very durable, as they did not wear, and ſeldom broke. The ſkin or pulp which ſurrounds the nuts, is uſed in America to waſh linen, but it is very apt to burn and deſtroy it, if often uſed, being of a very acrid nature.

[The ſeed-veſſels, ſays Dr. Patrick Browne are very deterſive and acrid; they lather freely in water, and will cleanſe more linen than ſixty times their weight of ſoap; but they are obſerved to corrode or burn the linen in time: and the water in which the tops or leaves have been ſteeped or boiled, have the ſame quality in ſome degree. The ſeeds are round and hard, have a fine poliſh, and are frequently made into buttons and beads among the Spaniards. The whole plant, eſpecially the ſeed-veſſel, being pounded and ſteeped in ponds, rivulets or creeks, is obſerved to intoxicate and kill the fiſh.

Loureiro celebrates the berries ſlightly bruiſed and ſteeped in water, as a very excellent ſoap, and remarks that it is only required to uſe them with prudence, all abſtergents being in ſome degree corroſive.

He deſcribes this as a large tree, whereas Browne ſays it ſeldom riſes above ten or fifteen feet in height in the ſavannas of Jamaica, where it is very common. According to Loureiro, it is both wild and cultivated

Digitized by Google

in Cochinchina: and our circumnavigators found it in Eaſter iſland in the South Seas. It was cultivated here in 1697 by the Dutcheſs of Beaufort [a].

2. Unarmed. Leaflets five pairs; the loweſt oppoſite ſmaller lanceolate-oblong; the outer alternate, four or five inches long broad-lanceolate: all quite entire, ſmooth, veined, ſhining above, paler beneath, ſharpiſh. Petioles roundiſh, equal; the partial ones ſhort. Raceme decompounded. Flowers cluſtered, on very ſhort pedicels. Calyx tomentoſe-hoary, four-leaved: leaflets ovate acute. Petals length of the calyx.—Suppoſed to be a native of the Eaſt Indies [a].

3. This ſpecies is very remarkable for the prickline ſs of its trunk, which ſeldom exceeds ſeven or eight feet in height, and two or three inches in diameter. The fruit is much ſmaller than that of the firſt, and though the embryos are always trilocular as in that, no more than one of the cells and ſeeds ever grows to perfection: the capſules however are marked with longitudinal ſutures, that run down between the two abortive embryos, which have been formed by the laceration of the ſtyle in the growth of one of the cells; for there is no more than one ſtyle in any of the flowers.

Native of Jamaica, in the borough of St. James's. Called there the Licca Tree [b].

4. Branches round, ſtriated, ſmooth. Leaves alternate, abruptly pinnate, three-paired: leaflets ſubopposite, ſhortly petioled, five inches long, the inner ones ſmaller, ovate-oblong or elliptic lanceolate, attenuated, quite entire, ſharpiſh, ſmooth on both ſides, veined, the inner ſhorter at the baſe. General petiole roundiſh: the partial ones wrinkled. Raceme ſuperdecompound. Peduncles and pedicels ſubpubeſcent. Bractes ovate, minute. Calyx five-leaved: leaflets ovate. Corolla five-petalled: petals oblong, villoſe, white-tomentoſe at the edge. Stamens eight, villoſe. Germ and fruit as in the next ſpecies.—Native of Malabar.

5. Unarmed. Branches round, almoſt as thick as the little finger, ſmooth, gray. Leaves alternate, abruptly pinnate, two-paired or three-paired: leaflets on very ſhort petioles, oppoſite, the middle ones alternate, two or three inches long, the inner ones ſmaller, ſcarcely unequal at the baſe acute, very blunt at the tip, emarginate, rigid, veined. General petiole roundiſh: partial ones ſhort, wrinkled. Raceme terminating, ſuperdecompound, large. Peduncles and pedicels ſpreading, pubeſcent. Bractes ſmall, ovate, at the baſe of the pedicels. Calyx five-leaved, pubeſcent: leaflets ovate, concave. Petals five, a little longer than the calyx, oblong villoſe on the outſide, ſmooth within, white-tomentoſe at the edge. Filaments eight, villoſe, length of the corolla. Germ tomentoſe. Style ſingle. Capſules three, ſubturbinate, coadunate; each ſubglobular, one or two frequently abortive, covered with denſe yellowiſh hairs: the cells within hirſute at the partitions. Seeds black. Aril none. Allied to the preceding ſpecies, but having narrower ſhorter leaves, very blunt, emarginate, and villoſe beneath.

Native of the Eaſt Indies; where it was obſerved by Koenig [c].

6. Trunk perfectly erect, of conſiderable length and thickneſs. Branches numerous, aſcending. Leaves alternate, abruptly pinnate, about a foot long. Leaflets oppoſite, four to ſix pair, entire, above ſmooth, below downy, about three inches long, and half an inch broad. Petiole round, downy, ending in a downy briſtle. Panicle terminating, large, erect, compoſed of ſimple racemes. Calyx five-leaved. Petals four, placed on the upper ſide. Style ſingle, aſcending, ſhorter than the ſtamens. Capſules three, (when all come to perfection, which is rare,) ſingly oblong, one-celled [d].

It differs from the preceding, in the leaflets being five-paired, longer, acute, not three-paired, emarginate: panicle compoſed of few racemes and divaricate, not ſuperdecompound and contracted: petals ſmooth. Native of the Eaſt Indies [e].

[a] Hort. kew. [b] Browne. [c] Vahl. [d] Roxburgh. [e] Willdenow.

It is a large timber tree, growing in the mountainous parts of the Circars; and flowering about the beginning of the hot ſeaſon. Known by the name of Iſhyraſhy among the Telingas. The wood is very uſeful for a variety of purpoſes, being large, ſtraight, ſtrong and durable: towards the centre it is of a chocolate colour [f].

7. Unarmed. Branches round, ſmooth, gray. Leaves alternate, abruptly pinnate, two-paired: the two inner leaflets alternate, the outmoſt oppoſite, three inches long, bluntiſh, veined, very ſmooth, pale green, quite entire, equal at the baſe. General petioles roundiſh: partial ſhort, wrinkled. Racemes ſeveral from the ſame point, having only a branch or two at the baſe, a finger's length, upright. Peduncles of permanent pedicels after the flowers fall toothed, becoming hoary, angular-ſtriated. Pedicels very ſhort. Bractes minute, ovate. Calycine leaflets five, ovate-roundiſh, ſhining like ſilk on the outſide. Petals five, longer than the calyx, oblong, ſmooth. Filaments eight, villoſe.

Native of the Eaſt Indies; where it was found by Koenig.

8. Unarmed. Branches round, gray, ſmooth. Leaves alternate, abruptly pinnate, three-paired: inner leaflets alternate, ſmaller; outer oppoſite, three inches long, ovate-oblong ſometimes ovate-lanceolate, attenuated, on one ſide narrower, quite entire, veined, ſmooth. Petiole equal, roundiſh, pubeſcent: partial ones ſhort. Raceme terminating, ſuperdecompound, a foot long: branches and branchlets ſpreading. Pedicels ſhort. Bractes minute. Flowers ſmall. Calyxes ſcarcely villoſe. Petals roundiſh, concave, ſmooth. Germ ovate, ſmooth [g].

Gærtner calls the fruit berried Drupes, fleſhy, from two to four, ſpherical, coadunate without any intermediate receptacle, having a ſhort upright dagger-point at top, of a red colour. Pulp thin, becoming towards the middle a white ſpungy tomentoſe ſubſtance, cloſely embracing the ſhell or nut; which is of a trigonal-globular form, and a bony ſubſtance, black, compoſed of horny horizontal fibres, two-celled, valveleſs; cells a little unequal, placed one behind the other. Seed in each cell one, obovate, angular, pale, adhering to the top.]

Miller deſcribes it as having a ſtrong woody ſtalk which riſes about twenty feet high, ſending out many ſhort ſtrong branches, covered with a ſmooth gray bark. Leaves compoſed of two pairs of ſpear-ſhaped leaflets, very ſtiff and ſmooth; the inner pair ſmall, ſeldom more than an inch and half long; the two outer near three inches long, and almoſt an inch broad in the middle, drawing to points at both ends; they are oblique to the foot-ſtalk, of a pale green, and ſit cloſe to the midrib. The ends of the branches are divided into two or three foot-ſtalks, each ſuſtaining a looſe ſpike of flowers. Berries roundiſh, generally two, three or four joined together.

[Native of the Weſt Indies. Cultivated in 1759 by Mr. Miller [h]: who ſays that it was diſcovered by Dr. Houſtoun at La Vera Cruz in New Spain; if ſo, he muſt have cultivated it much earlier.

9. A tree, of about ſeven or eight feet in height, and branching at the top: diameter eight or nine inches: bark rough and gray; wood whitiſh: branches knotty, and ſubdivided; ſpreading on all ſides: leaves alternate, winged: leaflets ovate, ending in a long point; ſmooth and of a bright green: midrib ſtrong, concave above, and convex beneath: the number of leaflets on each ſide is three: from the boſoms of the leaves proceed cluſters of flowers, which are very ſmall, and which could not be accurately deſcribed on account of their unadvanced ſtate.—Native of Guiana, where it was obſerved by Aublet.

10. A tree of about eight feet in height with a ſtraight ſtem of about two inches in diameter, and leafy at the top: bark rough and aſh-coloured: wood brittle and whitiſh: leaves alternate, pinnated, large: leaflets ovate-oblong, ſharp, entire; ſtanding ſomewhat alternately on a tough midrib which is concave

[f] Roxburgh. [g] Vahl. [h] Hort. kew.

above

above and convex beneath: the number of leaflets on each ſide the midrib is commonly ſeven; they are of a bright, ſhining green, and are placed on ſhort foot-ſtalks: the fruit is borne from the boſoms of the leaves, and is a dry, coriaceous capſule, of a beautiful red colour.

This ſpecies grows at Cayenne, where it was obſerved by Aublet, who did not ſee it in its flowering ſtate [i].

11. Unarmed. Branches round, ſmooth, with a dotted bark. Leaves abruptly pinnate, three-paired: leaflets petioled, almoſt oppoſite, nearly reſembling thoſe of Laurus Caſſia, three inches long, the inmoſt ſmaller, ſharp at both ends, acuminate, very ſmooth and even, obſcurely veined, glaucous beneath. Petioles flattiſh above, purpliſh, ſmooth. Racemes terminating, decompound; peduncles and pedicels ſlightly tomentoſe [k].

Loureiro ſeparates it from this genus, under the name of *Dimocarpus*, on account of its twin or double fruit; and he is followed by Willdenow. Loureiro deſcribes the Li-chi as a middle-ſized tree, with ſpreading branches. Leaves unequally pinnate, with about four pairs of leaflets, which are lanceolate, ſmooth, almoſt quite entire, glaucous beneath. Flowers pale, terminating, in oblong looſe racemes. Berry heart-ſhaped, with a ſcaly, thin, hardiſh rind, brown-red on one ſide, green on the other, and a white, ſweet, ſubacid, very pleaſant pulp. Seed brown, ſhining, regular, ſubovate, large. Calyx five-cleft, inferior, ſpreading, hairy; the ſegments rounded. Corolla wheel-ſhaped: petals five, oblong, hairy, almoſt equal to the calyx. Nectary one-leafed, whereas in Sapindus it is four-leaved. Filaments ſhorter than the corolla, placed on the receptacle. Anthers two-celled, roundiſh. Germ two-lobed, very hairy. Style thick, bifid, equal to the ſtamens. Stigmas oblong, reflexed. Berries two, one-celled, roundiſh, pulpy.

Gærtner has it under the name of *Scytalia*, and Schreber has followed him. According to Gærtner, the calyx is very ſhort, one-leafed; toothleſs, or very indiſtinctly five-toothed. Corolla five-petalled. Stamens from ſix to eight, with the filaments villoſe at the baſe, and the anthers two-lobed. Style ſimple, with a two-parted ſtigma. The fruit a juiceleſs berry, ſuperior, ovate-globular, of the ſubſtance and colour of parchment, rugged on the outſide all over with ſcutiform angular tubercles having a little point in their centre, ſmooth within, inflated, one-celled, brittle. Seed elliptic-globular, obliquely truncate at the baſe, where it is bare, of a pale red or cheſtnut colour, very ſmooth and ſhining, faſtened widely to the bottom of the berry, where it has a gentle riſing. The aril is ovate-globular, nearly the ſize of the cavity of the berry, very ſmooth, dark-coloured, fleſhy, thick, faſtened to the ſeed only about the baſe, in other parts looſe both from that and the pericarp: pulp ſoft, the conſiſtence of a damſon plum.

Native of China, Tunquin and Cochinchina. Introduced in 1786, by Warren Haſtings, Eſq.[l] Loureiro ſays that it is cultivated in great abundance in the ſouthern provinces of China, and the northern provinces of Cochinchina; being equally abhorrent both of cold and heat in the extremes.

The fruit of the Li-tchi is the ſize of a Date. Its ſtone, which is long and hard, is covered with a ſoft juicy pulp, that has an exquiſite taſte. This pulp is incloſed in a tough thin browniſh warty ſkin. This delicious fruit is ſaid to be dangerous when eaten to exceſs, occaſioning an eruption over the whole body. The Chineſe ſuffer it to dry till it becomes black and ſhrivelled like Prunes. Thus it is preſerved all the year, and they uſe it in tea, to which it communicates an acidity, which they prefer to the ſweetneſs of ſugar. To enjoy this fruit in its full perfection of flavour and ſmell, it muſt be eaten in the provinces Fo-ki-en, Quan-tong and Quan-ſi, where it grows. As it will not bear the climate of Pekin, the fruit is carried there for the Emperor's uſe, incloſed in tin veſſels, filled with ſpirits mixed with honey, &c. and thus preſerves an appearance of freſhneſs, but loſes much of its flavour [m]. The trees themſelves are alſo tranſported by water from Quan-tong to Pekin for the Emperor, at a conſiderable labour and expenſe to his ſubjects; and being embarked when they begin to flower, the fruit is commonly ripe by the time of their arrival at Pekin [n].

Loureiro has three other ſpecies of *Dimocarpus*, which Willdenow ſuppoſes may be varieties of this.—The firſt of theſe is the *Longan*, *Lang-an*, *Long-yen* or *Laong uban*, ſignifying Dragon's-eye; which is alſo cultivated in China and Cochinchina, and bears a fruit that is in much eſteem, and if not ſo agreeable to the taſte as the Li-tchi, is however ſaid to be more wholeſome. It is globular, has a yellowiſh ſmooth ſkin; and its pulp is white, tart and juicy [o].

His third ſpecies is the *Rampoſtan* of Bontius, (Jav. l. 6. c. 23. f. 109.) Which bears alſo an eſculent fruit. His fourth, does not bear a fruit that is eatable, but the wood is heavy, hard, of a reddiſh brown colour, and very excellent.

12. The branches, petioles and leaves of this tree are ſmooth. Leaves ſix-paired or thereabouts, a foot long: leaflets when young ſpreading, a finger's length [p]. Berries three, two of which are abortive, ovate, acuminate at both ends, three-ſided; the third very large, globular, with a prominent ſuture in the circumference, attenuated in front, fleſhy, thin, covered on the inſide with a ſmooth papery membrane: ſtone ovate, truncate as it were in front, and having a vertical umbilical cleft, unequally two-celled [q]. Thunberg informs us that the fruit was reported by the Japoneſe phyſicians to be bitter and juicy.

13. This is a large tree, with ſpreading unarmed branches. Leaflets lanceolate, ſmooth. Flowers pale, in large ſubterminating racemes. Calyx and corolla equal, bell-ſhaped, four-leaved and four-petalled. Style one, three-grooved: ſtigmas three. Berries three, connate, ſubglobular, one-ſeeded, rufous.—Native of China about Canton. Not having a thorny ſtem, or laciniate leaves, it muſt either be a diſtinct ſpecies, or thoſe characters are not conſtant [r].]

Mr. Miller has a ſpecies, which he names *Sapindus pinnatus*, and characterizes as having pinnate leaves, with ovate-oblong leaflets, the upper ones alternate. He deſcribes it as riſing with a ſtraight jointed ſtem to the height of twenty feet, ſending out ſome lateral branches at the top, covered with a pale ſmooth bark. The leaves are compoſed of eight or ten pairs of leaflets, each near four inches long, and an inch and half broad at their baſe, of a light green colour, on very ſhort foot-ſtalks; thoſe on the lower part of the midrib are oppoſite, but on the upper they are alternate, and end abruptly.—Native of India.

PROPAGATION AND CULTURE.

Theſe plants are propagated by ſeeds (which muſt be obtained from the countries where they naturally grow, for they have not produced fruit in Europe;) the ſeeds muſt be put into ſmall pots filled with rich freſh earth, and plunged into a hot-bed of tanner's bark. The pots muſt be frequently watered, otherwiſe the berries, whoſe outer cover is very hard, will not vegetate. In five or ſix weeks the plants will appear, when the glaſſes of the hot-bed ſhould be raiſed every day in warm weather to admit freſh air to the plants. In a month or ſix weeks after the plants appear they will be fit to tranſplant, when they muſt be ſhaken out of the pots, and carefully parted, ſo as not to injure their roots, and each planted into a ſeparate ſmall pot filled with light rich earth, and then plunged into the hot-bed again, obſerving to ſhade them from the ſun every day until they have taken new root; after which time they muſt have free air admitted to them every day when the weather is warm, and will require to be frequently watered.

After the plants are well rooted, they will make great progreſs, ſo as to fill theſe pots with their roots in a few weeks time, therefore they ſhould be ſhifted into

Digitized by Google

larger pots, and as the plants advance, they ſhould be inured to bear the open air by degrees; for if they are forced too much in ſummer, they ſeldom live through the winter. I have frequently raiſed theſe plants from ſeeds to the height of two feet in one ſummer, and the leaves of theſe plants have been a foot and a half in length, ſo that they made a fine appearance; but theſe plants did not ſurvive the winter, whereas thoſe which were expoſed to the open air in july, and thereby ſtinted in their growth, continued their leaves freſh all the winter. Theſe were placed in a ſtove upon ſhelves, where the warmth was very moderate, with which theſe plants will thrive better than in a greater heat.

The laſt ſort is much more hardy: this may be placed in a good green-houſe in the autumn, where it will live through the winter, and in ſummer ſhould be expoſed to the open air in a ſheltered ſituation, where it will thrive very well.

DESCRIP-

Digitized by Google

DESCRIPTIONS, &c.

1. Root perennial, ſtriking deep and ſpreading wide, and creeping by runners. Stems a foot and half in height, upright, round, rigid, jointed, ſmooth, often reddiſh, panicled at top. Leaves oppoſite, connate, quite entire, three-nerved, ſmooth. Panicle hemiſpherical, many-flowered, bracteolate. Corolla fleſh-coloured or roſe-coloured, varying to white, ſmelling ſweet. Petals entire, crowned at the throat. Seeds blackiſh, with a granulated ſurface [a].

Native of Europe, but not in the very northern parts. In England not uncommon, in paſtures and hedges: flowering from july to ſeptember.

It has both the Latin and Engliſh name, from its quality of forming, like ſoap, a lather with water, and taking out ſpots of greaſe, &c. from cloth, in the ſame manner; whence it has alſo been called the *Fuller's herb* [b].

The whole plant is bitter. A decoction of it applied externally cures the itch. The Germans uſe it inſtead of Sarſaparilla, in venereal complaints. M. Andry of Paris cured violent gonorrhœas, by giving half an ounce of the inſpiſſated juice daily. By the uſe of the extract, and a decoction of the leaves and roots, M. Jurine cured old venereal complaints, ſuch as ulcers, pains and emaciations, which reſiſted the uſe of mercury [c].

According to Dr. Woodville, a fancied reſemblance of the roots to thoſe of Sarſaparilla, ſeems to have led phyſicians to think them ſimilar in their effects.—Boerhaave, as Haller informs us, entertained an high opinion of its efficacy in jaundice and other viſceral obſtructions.]

β. A variety with double flowers is preſerved in gardens, but has the ſame fault with the ſingle one, of ſpreading very much at the root. [This was obſerved growing wild, by Mr. Lawſon, at Carnforth in Lancaſhire; and by Dr. James Sherard, in the road from Sittingbourn to Rocheſter. I have gathered it frequently on Streatham common in Surry. But in all theſe places it has probably eſcaped from gardens.]

γ. The roots of this do not ſpread like thoſe of the common ſort; the ſtalks are ſhorter, thicker, and do not grow ſo erect; they riſe a foot or more in height; the joints are very near and ſwelling: the leaves are produced ſingly on the lower part of the ſtalks, but towards the top they are often placed by pairs; they are about three inches long and two broad, having ſeveral longitudinal veins or plaits, and are hollowed like a ladle. The flowers are diſpoſed looſely on the top of the ſtalk, have large cylindrical calyxes, only one petal, and ſcarcely any viſible ſtamens; they are of a purple colour, and appear in july.

[I found this ſtrange kind of Gentian, ſays Gerarde, in a ſmall grove of wood called the Spinnie, near unto a ſmall village in Northamptonſhire called Lichbarrow. It was no longer there in Ray and Morton's time, but it has been preſerved in gardens. Mr. Miller, who in 1759 ſays that he had then cultivated it forty years, conſiders it as a diſtinct ſpecies. Ray regards it as a luſus naturæ, or a degeneration of the common Saponaria. Linneus, as a mule plant, like Antirrhinum Peloria; from a Saponaria paſſing into a monopetalous Gentian. Mr. Curtis inclines to Ray's opinion.]

2. This is an annual plant, riſing with an upright ſtalk near a foot and a half high, branching out upwards into ſeveral diviſions; theſe always are by pairs oppoſite, as are alſo the leaves, which are about an inch and a half long, and half an inch broad at their baſe, ending in acute points; they ſit cloſe to the ſtalks, are ſmooth, and of a gray colour. The flowers are produced at the end of the branches, each ſtanding upon a long naked foot-ſtalk; their calyxes are large, ſwelling and pyramidal, having five acute angles; the petals are but ſmall; they have long necks or tails, which are narrow; their upper part is obtuſe, and of a reddiſh purple colour. Theſe appear in june and july, and the ſeeds ripen in autumn.

[Capſule covered with the ſmooth calyx which is five-cornered at the baſe, ovate-conical, one-celled at top, three or four-celled at bottom, formed of a double lamina; the outer papery or cartilaginous, ſmooth, opening at top with four teeth; the inner ſpongy-membranaceous, white, very thin, burſting irregularly at top, but forming incomplete partitions below; theſe partitions are very narrow, and obvious only at the baſe of the capſule. Receptacle columnar, free above, ſlender, rough-haired with umbilical cords, a little longer than half the capſule. Seeds about twenty, ſubglobular, having raiſed indiſtinct dots very thickly ſcattered over them, dark-coloured.—In the preceding ſpecies, the capſule is one-celled, or by means of a very narrow partition viſible only at the baſe of the capſule divided into two incomplete cells. The form of the capſule alſo is more oblong in this and fuſiform-ovate [e].

Native of Germany, Switzerland, France and Italy. Cultivated by Gerarde in 1596 [f].]

β. Mr. Miller has a ſpecies, which probably is a variety of the *Vaccaria*. He deſcribes it thus:—It is an annual plant, with a ſtrong ſmooth ſtalk about two feet high. Leaves ovate-lanceolate, three inches long, and an inch and half broad near their baſe, half embracing the ſtem; the upper part of which divides into many branches, which are again ſubdivided into long naked peduncles, each ſuſtaining a ſingle flower. Calyx large, pyramidal, ſwelling, having five acute angles. Petals obtuſe, red.

Native of Spain. It flowers in june and july; and the ſeeds ripen in autumn.

[3. Stem brachiate or dichotomous, round, villoſe-viſcid, narrow, a foot high. Leaves linear-ſubulate, even. Peduncles axillary, ſolitary, one-flowered, ſtiff. Flower erect. Calyx five-cornered with three ſtreaks at the corners, one-leafed, oblong, acute, membranaceous between the teeth. Petals ſmall, entire.—Native of Candia or Crete, in dry places [g].

4. Stem two feet high, erect, jointed, ſtiffiſh, below ſmooth, above pubeſcent and viſcid. Leaves lanceolate; the lower ones ſmooth, the upper ones under the ramifications pubeſcent and viſcid. Peduncles axillary, ſolitary, one-flowered, capillary, looſe, ſpreading, ſmooth, the length of the leaves, hanging down when in fruit. Calyx oblong, tubular. Petals without any crown, ſlightly fleſh-coloured, emarginate with ſhort ſegments. Stamens white, ſhorter than the tube. Germ ovate. Styles diſtant. Stigmas ſimple [h].

Native of the Levant. Annual.—Introduced in 1777, by Abbé Noſin. It flowers in july and auguſt [i].

5. This is an upright plant, a ſpan high, viſcid and pubeſcent. Leaves linear-lanceolate, ſmooth. Calyxes half-five-cleft, membranaceous at the edge. Petals entire, white with three purple dots. Anthers violet. Obſerved in Illyria by Arduini [k].

6. This is an elegant plant, with a perennial root, and many proſtrate or procumbent ſtems, which are dichotomous, knotted and pubeſcent. Leaves oppoſite, quite entire, pubeſcent: the lower ones ovate, blunt, petioled; the upper ones lanceolate. Flowers numerous, in terminating corymbs. Peduncles villoſe, filiform. Calyx tubular, with five ſmall erect blunt teeth. Petals roſe-coloured, ſpreading horizontally, oblong-elliptic, gradually wider from the baſe upwards, quite entire but ſometimes ſlightly emarginate, with a claw the length of the calyx, having two little appendages at the top. Capſule ovate-oblong, covered by the calyx, half-four-valved, one-celled, containing many brown kidney-form ſeeds. Receptacle columnar, free [l].

Native of Italy, Auſtria, Switzerland, France and Barbary, on mountains, covering the rocks with beautiful large tufts of flowers. Ray obſerved it by the Arve and Rhone near Geneva, and between Maſſa and Lucca in Italy.—It was introduced here in 1768, by Profeſſor de Sauſſure, and flowers from may to july [m].

Digitized by Google

I ſaw it in flower during the month of april (1779) about Chatelaine near Geneva.

7. Like the preceding, but with linear-lanceolate leaves; whereas in that they are lanceolate-ovate. Calyxes of the fruit ovate, with raiſed dots bearing hairs ſcattered over them. Petals acutely emarginate, without any crown.]

It is a low annual plant, ſeldom riſing more than four inches high; dividing into ſpreading branches by pairs from the bottom. Leaves very ſmall. Flowers ſingle from the axils. Calyxes hairy, cylindrical; out of which the petals do but juſt peep. The whole plant is very clammy.

Native of the Levant, whence Tournefort ſent the ſeeds. [Found ſince alſo in Gorizia, according to Scopoli.—Cultivated in 1732, by James Sherard, M. D.[f]

8. Root woody, crooked, branched, forming tufts. Stems ſeveral, weak, nearly upright, a finger's length, with three or four joints, leafy, round, downy. Leaves obtuſe, entire; thoſe next the root cluſtered, fading but permanent, ſmooth; thoſe on the ſtem oppoſite, ſeſſile, almoſt united at their baſe, ſlightly hairy. Corymbs terminating, denſe, many-flowered. Flower-ſtalks ſimple or trifid, ſhort. Bractes like the leaves, but ſmaller, in pairs at the baſe of the flower-ſtalks, hairy. Calyx cylindrical, hairy, purple in the upper part. Petals ſcarcely marked with a crown, violet at the baſe; the border obovate, entire, yellow. Five of the ſtamens as long as the border, and five ſhorter: filaments dark purple tipped with yellow: anthers yellow. Germ in the bottom of the calyx, oval, ſmall, green, marked with tubercles at the top. Styles as long as the longer ſtamens, white, permanent. Capſule oval, ſmooth, four-valved and one-celled. Seeds kidney-ſhaped, yellowiſh brown, minutely dotted.

Allioni firſt deſcribed this plant, juſtly obſerving that it was diſtinct from *Globularia lutea montana* of Columna, whoſe figure of that plant is excellent: nevertheleſs Linnæus and Haller united them under one ſpecies. Dr. Smith obſerved in Vaillant's herbarium ſuch important differences between them, that he had no doubt of their being perfectly diſtinct.

S. lutea is native of the mountains of Switzerland and Savoy. Dr. Smith found it in the fiſſures of rocks on mount Cenis, in auguſt 1787; where it was pointed out to him by Dr. Bellardi of Turin.

9. The radical leaves are ſpatulate, ending in a point very like thoſe of a Globularia. Stems thrice as tall as thoſe of S. lutea, and ſmooth. Stamens yellow, not purple. Petals, according to Columna's figure, linear, notched at the top. This very rare plant was gathered by Columna on the ſummits of ſome mountains in Italy[g].]

PROPAGATION AND CULTURE.

Theſe plants are eaſily propagated by ſeeds, ſown where they are to remain, kept clean from weeds, and thinned where they are too cloſe. If the ſeeds are ſown in autumn, or are permitted to ſcatter, the plants will come up of themſelves.

The double variety will increaſe faſt enough by its creeping roots, and will thrive in any ſituation.

The hollow-leaved Soapwort is eaſily propagated by parting the roots in autumn, and loves a moiſt ſhady ſituation.

[This affords little ſeed, but may be increaſed by ſlips or cuttings. It is a hardy perennial, loves a pure air and dry ſituation, grows beſt among ſtones, or out of a wall, and is one of the beſt plants for ornamenting rock-work[h].

DESCRIPTION, *&c.*

This is an annual plant, and looks extremely like the Whortle-berry buſhes (of America) when they firſt begin to look green, and whilſt the points of the leaves are yet red[k]. Stem and branches very much branched (ſubtrichotomous); leaves very ſmall, narrow and awl-ſhaped[l], (or linear.) Flowers axillary, ſolitary, ſeſſile. Capſule ſmall, membranaceous, ferruginous-red, ſubcylindrical, but very much attenuated and acuminate at the top, tubercled all over with the impreſſions of the ſeeds. Seeds ſubcylindrical, very finely ſtriated both lengthwiſe and acroſs, pale ſulphur-coloured, hanging from the inner margins of the valves, by ſetaceous umbilical cords[m].

Native of Virginia, Pennſylvania and Philadelphia, growing abundantly in the fields, and under the buſhes, in a dry ſandy ground, near the capital of the latter province.

It is reckoned a good traumatic[n]. Introduced here by Mr. John Bartram in 1768. It flowers in july[o].]

DESCRIPTIONS, &c.

1. Leaves near three feet high, ſmall at the bottom, but widening gradually to the top: they are hollow, and arched over at the mouth like a friar's cowl. The flowers grow on naked pedicels, riſing from the root to the height of three feet, and are of a green colour.

Native of Carolina, Virginia, &c. upon bogs, and in ſhallow ſtanding waters. [Cultivated in 1752, by Mr. Miller. It flowers in june and july [p].

2, 3. Both natives of Carolina, in bogs and wet places [q].]

4. The fourth ſort grows naturally upon bogs in moſt parts of North America; this has a ſtrong fibrous root, which ſtrikes deep into the ſoft earth, from which ariſe five, ſix, or ſeven leaves, in proportion to the ſtrength of the plant; theſe are about five or ſix inches long, hollow like a pitcher, narrow at their baſe, but ſwell out large at the top; their outer ſides are rounded, but on their inner ſide they are a little compreſſed, and have a broad leafy border running longitudinally the whole length of the tube; and to the rounded part of the leaf there is on the top a large appendage, or ear ſtanding erect, of a browniſh colour; this ſurrounds the outſide of the leaves about two thirds of the top, it is eared at both ends, and waved round the border. From the centre of the root, between the leaves, ariſes a ſtrong, round, naked footſtalk, about a foot high, ſuſtaining one nodding flower at the top: the leaflets of the upper calyx are obtuſe, and bent over the corolla, ſo as to cover the inſide of it; they are of a purple colour on the outſide, but green within only having purple edges: the petals are of a purple colour, and hollowed like a ſpoon. Germ large, channelled: ſtigma green, with the five corners ſtretched out beyond the brim, each cut into two points and purpliſh. Anthers target-ſhaped, furrowed, of a pale ſulphur colour. Capſule large, covered by the permanent ſtigma.

The hollow parts of the leaves have always water ſtanding in them, and the top or ear is ſuppoſed in hot dry weather to ſhrink, and fall over the mouth of the tube, and ſerve as a lid to prevent the exhalation of the water. In great droughts birds and other animals repair to theſe plants. In ſpring the leaves are of a dark green colour, but gradually change purpliſh, and towards autumn become dark brown.

The Engliſh, who firſt ſettled in North America, gave this plant the name of Side-ſaddle flower, from the reſemblance of the ſtigma to a woman's pillion.

[In the thirteenth edition of the Syſtema Vegetabilium the leaves of this ſingular plant are deſcribed as ſeſſile and cowled, with the tube bellying and widening gradually; the throat contracted a little with the margin in front dilated; the border kidney-ſhaped, ſpreading, emarginate; the belly in front with a membranaceous, ſemielliptic, two-nerved keel. Such is the metamorphoſis of the leaf of Nymphæa into that of Sarracenia, in order that, by receiving and retaining rain water, it may grow out of the water; a wonderful proviſion of Nature!

Introduced before 1640, by Mr. John Tradeſcant, junior, who, as Parkinſon informs us, found it in Virginia, brought it home, and cultivated it.]

PROPAGATION AND CULTURE.

Theſe plants are eſteemed for the ſingular ſtructure of their leaves and flowers, which have little reſemblance of any yet diſcovered; but there is ſome difficulty in getting them to thrive in England, when they are obtained from abroad; for as they grow naturally on bogs, or in ſhallow ſtanding waters, ſo unleſs they are conſtantly kept in wet, they will not thrive; and although the winters are very ſharp in the countries where the fourth ſort naturally grows, yet being covered with water and the remains of decayed plants, the plants are defended from froſt.

The beſt method to obtain theſe plants is, to procure them from the places of their natural growth, and to have them taken up with large balls of earth to their roots, and planted in tubs of earth; they muſt be conſtantly watered during their paſſage, otherwiſe they will decay before they arrive; for there is little probability of raiſing theſe plants from ſeeds, ſo as to produce flowers in many years, if the ſeeds do grow; ſo that young plants ſhould be taken up to bring over, which are more likely to ſtand here, than thoſe which have flowered two or three times. When the plants are brought over, they ſhould be planted into pretty large pots, which ſhould be filled with ſoft ſpongy earth, mixed with rotten wood, moſs, and turf, which is very like the natural ſoil in which they grow. Theſe pots ſhould be put into tubs or large pans which will hold water, with which they muſt be conſtantly ſupplied, and placed in a ſhady ſituation in ſummer; but in the winter they muſt be covered with moſs, or ſheltered under a frame, otherwiſe they will not live in this country; for as the plants muſt be kept in pots, ſo if theſe are expoſed to the froſt, it will ſoon penetrate through them, and greatly injure,

[p] Hort. kew. [q] Walter. [r] Mill. fig. [s] Hort. kew.

Digitized by Google

if not deſtroy the plants; but when they are placed under a common frame, where they may have the open air at all times in mild weather, and be ſheltered from hard froſt, the plants will thrive and flower very well.

Peduncles axillary three-flowered, involucres linear, leaves lanceolate-ovate quite entire.]

DESCRIPTIONS, &c.

1. This has very ſlender woody ſtalks, which grow erect, about nine inches high, ſending out two or three ſlender ſide branches towards the bottom. Leaves oppoſite, ſtiff. Flowers in whorls for more than half the length of the ſtalk, ſeeming as if they were bundled together. Corolla ſmall and white. The whole plant has a pleaſant aromatic ſmell.

[Native of Italy. Cultivated in 1739, by Mr. Miller. It flowers from may to ſeptember[t].]

2. This riſes about two feet high with a woody ſtem, and divides into many branches, ſo as to form a ſmall buſh. Leaves ſomewhat like thoſe of common Savory, having a ſtrong aromatic ſcent when bruiſed.

[Whorls in this ſpecies four or five, whereas in the preceding there are nineteen or twenty[u].

Native of the iſland of Candia. Cultivated in 1739, by Mr. Miller[x]; who has omitted it in the later editions of his Dictionary.

3. In appearance this agrees with S. montana or Winter Savory; from which however it differs in having the leaves leſs mucronate, but eſpecially in the corymbs of flowers, which are not ſingle on each ſide but double; the bractes alſo (or involucre) are very ſmall in this, but in that they are the length of the corymb. The lower leaves are ovate, like thoſe of Thyme, purpliſh beneath, the reſt are rather linear; on the upper ſurface of the leaves appear a ſort of ſparkling atoms, ſhining from a few ſhort ſcattered hairs. Corollas purpliſh on the outſide, on the inſide whitiſh-purple, with three purple ſpots at the baſe, the middle one larger than the others. After the firſt year the corymbs become ſolitary.—Native of the Archipelago[y], and the county of Nice.]

Digitized by Google

Mr. Miller says it has slender woody stalks which rise near a foot and half high, with small, ovate, stiff, acute-pointed leaves, having reflexed borders. Flowers in roundish whorls upon foot-stalks, by pairs from the axils, small and white, appearing in july.

Cultivated by Mr. Miller in 1759.

4. This is well known under the name of Winter Savory; and is a perennial plant, with a shrubby low branching stalk; the branches rise about a foot high, are woody, and have two very narrow stiff leaves, about an inch long, opposite at each joint: from the base of these come out a few small leaves in clusters. Flowers axillary upon short foot-stalks, shaped like those of the Summer Savory, but larger and paler. They appear in june, and the seeds ripen in autumn.

[The lower leaves are flattish, those under the flowers keeled. Lower peduncles three-flowered; the upper ones five or seven-flowered. The outer flowers have keeled bractes the length of the tube of the calyx. Throat of the calyx not contracted, hairy within. Corolla twice as large as the calyx and more. Filaments curved in under the upper lip, and of the same length with that lip. It has the same smell with S. hortensis, but weaker [z].

Native of the South of France and Italy. Cultivated here in 1562, as appears from Turner's herbal [a]. That is as far back as we have any printed registers; for there can be no doubt but that this and Summer Savory, with other pot-herbs, were much cultivated in far earlier times, before the spices from the East Indies were known and in common use.]

5. Summer Savory is an annual plant, with slender erect stalks about a foot high, sending out branches at each joint by pairs. Leaves opposite, about an inch long, and one eighth of an inch broad in the middle, stiff, a little hairy, and having an aromatic odour if rubbed. Flowers towards the upper part of the branches, axillary; each peduncle sustaining two flowers. Corolla pale flesh-colour.

[Native of the South of France and Italy. Cultivated here in 1562. Flowers from june to auguft [b].] Seeds ripen in autumn.

6. This has a low shrubby stalk, which sends out branches on every side, about six inches long and hoary. Leaves stiff, narrow, acute-pointed. Flowers in short roundish spikes at the end of the branches, small and white. The whole plant is hoary and very aromatic. It never produces seeds in England.

[Native of the Levant. Cultivated in 1640, as appears from Parkinson. It flowers from june to october [c].

7. This is a shrubby species, native of Candia or Crete; distinguished by its thorny branches, and shaggy leaves.

8. This is a shrub from two to twelve feet in height, with an upright stem, very much branched and loose. Branches four-sided, strict, subdivided, long; with the branchlets four-cornered, striated, loose, directed one way, ferruginous-pubescent. Leaves opposite, approximating, small, oblong, wedge-shaped, sometimes ovate, convex, sometimes flat, nerved, somewhat rugged, hoary beneath. Petioles short. Leaflets in the axils of the larger leaves. Flowers subsessile at the ends of the branchlets, by threes, the length of the leaves, white. Under the flowers a few linear leaflets, called by Linneus the involucre. Calyx five-cleft, ten-streaked, five-cornered, hispid, hoary: segments almost equal; the two upper ones approximating, acute, linear, erect. Tube of the corolla scarcely longer than the calyx: upper lip or two upper segments shorter, erect, approximating, less divided, ovate; lower lip or three lower divisions nearly equal, the two lateral ones ovate, the middle one roundish, concave, bent in. Filaments inserted into the middle of the tube, which is villose, two of them shorter than the tube: anthers distant, roundish, black. Germ ovate: style longer than the tube, awl-shaped: stigma simple, acute, bent in.

Native of the cooler mountains of Jamaica; flowering there in autumn.

There are two varieties: one a shrub, smaller and more rigid, with smaller oblong leaves: the other a little tree, twelve or fifteen feet high, with the branches loose and rounder leaves.

The whole plant is very sweet-scented, even when dry [d].

Introduced in 1783, by Matthew Wallen, Esq. [e]]

PROPAGATION AND CULTURE.

4. Winter Savory may be propagated by seeds in the same way as Summer Savory, or by slips, which, if planted in the spring, will take root very freely. It is very hardy, and will continue several years, especially on a poor dry soil, or on a wall: but when the plants are old, the shoots are short, and not so well furnished with leaves; it will be proper therefore to raise a supply of young plants every other year.

5. Summer Savory is only cultivated by seeds, sown at the beginning of april, upon a bed of light earth, where they are to remain, or for transplanting: if the plants are to stand unremoved, the seeds should be sown thinly. Keep them clean from weeds, and treat them in the same way as Marjoram.

1, 2; &c. The other sorts are too tender to live through the winter in the open air in England. They are generally propagated by slips or cuttings, which take root very readily during any of the summer months. If they are planted in a shady border, or are shaded from the sun with mats, they will be fit to be transplanted in two months, when they should be taken up carefully, and each put into a small pot filled with fresh undunged earth, and placed in the shade till they have taken new root: then place them in a sheltered situation, where they may remain till the end of october, when they should be placed under a common hot-bed frame, where they may be exposed to the open air at all times when the weather is mild; but they must be protected from hard frost.

As these plants seldom live above three or four years, there should be a supply of young ones raised to preserve the species. In winter they should not have much wet, for they are very subject to grow mouldy, especially if the air be excluded from them: or if the branches be drawn up weak, they become mouldy and soon decay.

[SATUREIA. See *Cunila*, *Thymbra*, *Thymus*.]

SATYRIUM. (*Σατυριον of Dioscorides.* Satyrium *of Pliny. So named from the supposed libidinous property of the root.*)

Lin. gen. n. 1010. *Reich. n.* 1095. *Schreb. n.* 1368. *Juss.* 65.

Class. 20. 2. Gynandria Diandria.

Nat. order of *Orchideæ*.

GENERIC CHARACTER.

CAL. *Spathes* wandering. *Spadix* simple. *Perianth* none.

COR. *Petals* five, ovate-oblong: three exterior; two interior converging upwards into a helmet. *Nectary* one-leafed, annexed to the receptacle by its lower side between the division of the petals: upper lip erect, very short; lower flat, pendulous, prominent behind at the base in a serotiform bag.

STAM. *Filaments* two, very slender and very short, placed on the pistil. *Anthers* obovate, covered by the two-celled fold of the upper lip of the nectary.

PIST. *Germ* oblong, twisted, inferior. *Style* fastened to the upper lip of the nectary, very short. *Stigma* compressed, obtuse.

PER. *Capsule* oblong, one-celled, three-keeled, three-valved, opening in three parts under the keels, cohering at the top and bottom.

SEEDS numerous, very small, irregular like saw-dust.

ESSENTIAL CHARACTER.

Nectary serotiform or twin-inflated behind the flower.

DESCRIPTIONS, *&c.*

1. Lizard Satyrion or Goat Orchis, called by our old authors the Lizard flower from its ſpotted corolla, and great Goat's-ſtones, from the ſcent of the flower, and the large teſticulated roots, is the talleſt Engliſh plant of this tribe, frequently attaining the height of three feet, and producing from twenty to ſixty or more flowers, remarkable for their fetid goat-like ſmell. The upper part of the lip is downy, and marked with elegant purple ſpots on a white ground; otherwiſe the flowers are more ſingular than beautiful [f.]

The leaves are near five inches long, and half an inch broad. The ſpike of flowers is ſix inches in length: the corolla of a dirty white, with ſome linear ſtripes and ſpots of a brown colour; the middle ſegment of the lip of the nectary is two inches long.

[Native of Germany, Switzerland, Auſtria, France, Italy, and England in the county of Kent, about Dartford; flowering, according to Ray, from the end of may to the middle of june; others mark july for its month of flowering. It loves a chalky ſoil, at leaſt with us, and a ſhaded ſituation among ſhrubs and tall graſs. It ſeems to have been firſt obſerved by Mr. Bowles, in the way from Crayford to Dartford; afterwards by Mr. Rouſe, an ingenious botaniſt, and eminent apothecary in London, near Dartford [g]. It has ſince been occaſionally met with in that neighbourhood, but the greedineſs of collectors has frequently endangered its total deſtruction, and in ſome ſeaſons none can be found in flower [h].

This plant varying in ſize and the breadth of the leaves, has given occaſion to old authors to make two ſpecies of it. The flowers are ſometimes quite white.

2. Found by Thunberg, at the Cape of Good Hope, on the top of the Table mountain; whence its trivial name.

3. Large and panicled. Found by Thunberg at the Cape.

4. This is a fathom in height, with large orange-coloured flowers.

5. The lip is muricate with white and purple prickles. Both theſe were alſo found by Thunberg at the Cape [i].

6. Frog Satyrion, commonly called Frog Orchis, has a ſtem from five to eleven inches high and ſolid, with unequal ſharp angles, formed from the edges of the leaves and bractes. Spike lanceolate, from one to three inches long, looſe with few flowers. Bractes ſubulate-lanceolate, keeled, ſomewhat bowed in. Tube of the calyx inveſting the germ; border with three diviſions; ſegments ovate, nearly equal, with ſharp longitudinal wrinkles, approaching upwards, before flowering glued together, and involving all the parts of fructification, except the nectary; the ſide ones more convex on the outſide, bowed back ſideways at the points, the middlemoſt rather ſmaller, more bent inwards. Theſe, which are clearly an extenſion of the ſkin inveſting the germ, incloſe as a calyx the other parts of fructification, and are of a texture ſimilar to that of the bractes. Corolla of three petals, the two upper linear-lanceolate, concave, upright, of a greeniſh whitiſh hue, as long as the calyx, inſerted at the diviſions at the baſe of the upper lip of the third petal. Theſe are of a different texture from the calyx, are ſituated within it, and exactly reſemble the texture of petals. The third petal gaping, with two lips, ſurrounding the edge of the germ; upper lip roundiſh, concave, reddiſh brown, as ſhort again as the two upper petals, divided within into two cells, each containing one of the ſtamens, compoſed of four valves, marked at the baſe with a fleſhy tooth; lower lip oblong-linear, bent back, ſomewhat longer than the calyx, flat, of a yellowiſh greeniſh hue, the ſides and end tinged with browniſh purple, the edges bent in at the baſe, with a longitudinal ridge running along the middle, cloven into three at the end, the lateral ſegments linear, bluntiſh, the middlemoſt very ſhort, projecting underneath at the baſe into a nectary. This is to be conſidered as a petal, from its ſimilarity to that of the Fumaria, and the whole claſs of Perſonatæ, which it exactly reſembles. Nectary roundiſh, ſlightly furrowed along the middle, concave, hanging down from the baſe of the lower lip of the corolla. In Fumaria and the Perſonatæ, the nectary, as here, is an expanſion of the petals, containing a honey-like juice. Anthers unchanged on being moiſtened with water, and not containing any viſible pollen [k].

The roots have but few diviſions. The lower leaves ſheath the ſtem, are oval, broad, marked with parallel veins, and irregularly reticulated with croſs ones, ſmooth but not ſhining; ſtem-leaves lanceolate, the upper ones ſeſſile. Bractes lanceolate, reſembling the upper leaves, much longer than the germ and flower [l].

Native of many parts of Europe, eſpecially in the northern countries, in meadows and paſtures, chiefly in a gravelly or rocky ſoil with us; alſo in Siberia. It flowers from the end of may to the beginning of auguſt.—King's-hedges near Cheſterton, and Cherry-Hinton, Cambridgeſhire; Stevington, Thurleigh, Bletſoe, Pertenhall, Luton Hoo, Bedfordſhire; in the way to Glenfield from Leiceſter; Braybrook, and Foſter's Booth in Northamptonſhire; Shotover-hill, South Leigh, Cornbury, and Burford Downs, Oxfordſhire; Thaxted in Eſſex; on Hellſe-fellhap near Kendal; alſo in Dorſetſhire, Yorkſhire and Scotland, not uncommon, but rarely in any quantity together.—It was firſt obſerved in England by Ray before 1660, in cloſes north of Cheſterton near Cambridge [m].

Ray has remarked that the lip of the flower varies to a duſky purple or ſooty colour; hence, and from the middle ſegment varying in ſize, which is a common accident in this tribe, Mr. Hudſon has deſcribed a Satyrium fuſcum [n].—Variety β. of Linnæus, figured by Vaillant, is ſaid to have larger flowers, and longer bractes [o].]

7. Stem about nine inches high. Leaves on the lower part about four inches long, but on the upper part ſcarcely an inch, embracing the ſtem at the baſe. Flowers in a thick ſhort ſpike, of a dark purple colour, [ſmelling very ſweet. Petals ſpreading. Lip undivided, ovate-lanceolate, crenulate. Spur very ſhort [p].

Native of the mountains of Lapland, Switzerland, Auſtria, Dauphiné and Savoy.

Said in the Kew catalogue, to be introduced in 1779, by the Rev. Samuel Goodenough, L.L.D. Mr. Miller had cultivated it in 1759, if not before; but this, like its congeners, is a fugitive plant in gardens; and Villars ſays of this ſpecies, that although it is very common in Dauphiné, they have not been able to cultivate it there.

8. Stem nine to fifteen inches high. Lower leaves oval, ſheathing the ſtem; upper lanceolate, acute. Flowers very numerous, in a long (an inch and half, cylindrical,) cloſe ſpike. Bractes lanceolate, very acute, longer than the germ. Petals white, oval-lanceolate, all converging: lip of the nectary ſhort, green, divided into three acute ſegments, the middle one longeſt and more blunt. Spur blunt, about half as long as the germ [q].

Stem ſcarcely a foot high, roundiſh, leafy. Leaves light green, rather glaucous beneath. Flowers ſmall, greeniſh-white, almoſt inodorous. Petals concave, all nearly equal. Lip green, palmate, with three lobes, of which the middle one is larger, and ſometimes

Digitized by Google

blunter than the other. Spur longer than in moſt of the genus, ſo as almoſt to make it an Orchis according to Linneus's rules; and it certainly has great affinity with ſeveral of that genus in other reſpects[r]. Hence Haller ſeems juſtified in not ſeparating theſe plants from the Orchides[s].

Native of Scania, Denmark, Germany, Switzerland, Anſtria, Dauphiné, Piedmont, Piſtoia, England, Scotland and Wales, on elevated expoſed graſſy hills, or dry mountainous paſtures: as upon the mountains north of Helmſley, by Mr. Teeſdale, in Yorkſhire; at the iſthmus of Tarbat, in Cantire, Argyleſhire; in the iſle of Arran, near Loch-Ranſa, &c. in Jura, Iſla, Colonſa and Skye, by Mr. Lightfoot; in the ſame places as Orchis conopſea, by Dr. Hope; Hafod in Cardiganſhire, by Miſs Johnes. It flowers in june and july. Cultivated by Mr. Miller in 1759.

9. Root tender, branched like coral, ſnow-white. Stem very tender, leafleſs, purpliſh in the upper part, covered with ſcales, about half a foot high, terminated by three or four white diſtant flowers. Nectary ſhort, compreſſed, recurved. Lower lip turned upſide down, oval, entire, with two lateral appendages, and two lines villoſe and coloured within. The other five petals linear, lanceolate, and yellowiſh[t].—Native of Auſtria, Dauphiné, and Siberia.

10. Native of Jamaica[u].

11. Roots filiform, long, tomentoſe. Stem a foot high, aſcending, nearly erect, round, leafy, very ſmooth. Leaves ſharp, entire, very ſmooth, nerved longitudinally, bright green and ſhining. Sheaths ſurrounding the ſtem, cowled, nerved, netted, membranaceous. Spike many-flowered, (fifty) upright. Flowers ſmall, white. Spathes ovate, half-embracing, membranaceous, acute. It has the flower of an Orchis, with the habit of a Satyrium. The horn is not teſticulate, but elongated, obovate, like a bladder and free, by Jacquin and others called the lower lip; but the lip is certainly trifid, with the middle ſegment acuminate[x].

Native of Jamaica and Martinico, in moiſt woods and ſhady places.

12. Native of Jamaica and Hiſpaniola[y].

13. Stem twelve or fourteen inches high, without leaves. Flowers fleſh-coloured, oblong and ſucculent[z]. Native of Jamaica and Hiſpaniola.

14. Native of Jamaica.

15. Native of Jamaica and Hiſpaniola[a].

16. Roots perennial, truly creeping, not bulbous, very ſucculent, downy, running among moſs, and attaching themſelves to decayed fragments and leaves of Fir, in the manner of Fungi. Leaves in tufts at the end of each runner, on broad ſheathing footſtalks, ovate, ſucculent, ſtrongly five or ſeven-ribbed, and reticulated with tranſverſe veins which are often brown, and the leaves are now and then prettily chequered with that colour. Stalks erect, ſix or eight inches high, round, downy upwards, clothed with a few alternate ſheathing bractes, and terminated with an erect ſpike of numerous pale fleſh-coloured fragrant flowers, leaning one way, but turning a little ſpirally round the ſtalk; each being accompanied by a lanceolate, concave, coloured, downy bracte, longer than the germ, which alſo is clothed with viſcid downineſs, as well as the three broader external petals. Haller deſcribes the flower as having only three petals beſides the nectary; but Mr. Sowerby obſerved two internal lanceolate petals, which, like thoſe of Orchis uſtulata, are very difficult to be detected in a dried ſpecimen, being glued as it were to the upper one, which the others are not, though Haller ſays they are[b].

Native of Lapland, Norway, Denmark, Switzerland, Auſtria, Siberia, Scotland; in Alpine Fir foreſts: flowering from june to auguſt.—Roſs-ſhire, two miles from the head of Little Loch-Broom, by Mr. Lightfoot. Oppoſite to Moy-hall, on the ſouth ſide of the road to Inverneſs. In a wood near Gordon caſtle, by Dr. Hope.

[r] Engl. bot. [s] Woodward. [t] Villars. [u] Swartz prodr. [x] Swartz obſ. [y] Swartz prodr. [z] Browne. [a] Swartz prodr. [b] Engl. bot.

Mentzelius mentions a variety, the leaves of which are ſpotted with black and white; which is not uncommon among the Orchideæ.

17. Root-leaves linear-lanceolate, ſlightly ſtriated, ſtrict. Scape-leaves alternate, embracing and ſheathing, acuminate, ſhorter. Raceme looſe. Bractes lanceolate, ſmaller. Peduncles the length of the flowers. Petals five, almoſt equal, lanceolate, beſides the lip, which is very blunt and emarginate, with a blunt tooth in the middle on each ſide. Spur very ſhort, blunt.—Native of the Cape of Good Hope.

18. Culm a foot high, with a few mucronate ſheaths. All the leaves radical, linear, the length of the culm below the ſpike. Spike oblong, with about ſixteen flowers thinly diſpoſed. Firſt petal cowled, gaping, very broad, finiſhing behind in a very ſhort horn: ſecond and third obovate; the two petals of the genitals under the firſt, ſmall, curved in: lip ovate, acute.—Found at the Cape by Thunberg.

19. This plant rather reſembles an Orobanche than an Orchis. Leaves linear, cauline. Spike longer than the ſtem, bifarious, denſely imbricate. Helmet of the corolla one-leafed, blunt, two-lobed at the back, putting forth behind two very ſhort bluntiſh horns. Lip obcordate, concave, diſtinct. Receptacle of the ſtamens oblong, under the helmet; at the top with a two-lobed lip, and two teeth at the baſe, which are ſubulate, like a nectary.—Found at the Cape by Sparrmann.

20. Culm a foot high, with a ſingle leaf in the middle. Leaf ſheathing, lanceolate-ſubulate. Spike oblong. Bractes chaffy, ſubulate. Flowers peduncled. Corolla conſiſting of five nearly equal petals.—Found at the Cape by Sparrmann[d].

21. Leaves lanceolate, ſpotted. Spike denſe, ſhort, blunt. Bractes ovate-oblong, acute, ſhorter than the germ. Flowers ſmall: the upper ſegments converging, acute, pale: lip pendulous, trifid; ſegments linear, very narrow, with the middle one longer and wider. Native of Atlas near Belide[e].]

PROPAGATION AND CULTURE.

Theſe plants are difficult to propagate. The beſt way to obtain them, is to take up their roots, and tranſplant them into the garden, with a good ball of earth, putting them into a ſoil as near to that in which they naturally grow as poſſible, and to leave the ground undiſturbed; for if their roots be injured, the plants ſeldom thrive afterwards. For the management of theſe plants, ſee ORCHIS.

DESCRIPTION, *&c.*

Root fibrous, perennial. Stalks generally traiſing, and ſeldom riſing more than two feet high, having ſome longitudinal furrows. Leaves heart-ſhaped and ſmooth, about three inches long, and two broad at their baſe, ending in obtuſe points, and having ſeveral longitudinal veins, which join at the foot-ſtalk, but diverge from the midrib towards the borders in the middle, and join again at the point; they ſtand upon foot-ſtalks about an inch long, and are alternate. Spikes axillary towards the top of the ſtalk, taper, and about two inches long. They appear in july, but are not followed by ſeeds in England. The ſtalk decays in autumn.

[Scales of the ament petioled, white, when going out of flower greeniſh, with the pedicels curved in to the rachis, and incumbent on the germ. The ſtamens can ſcarcely be numbered, unleſs they continue after flowering.

Native of Virginia[f]. Mr. Miller ſays it grows naturally in moſt parts of North America. He cultivated it in 1759[g].]

PROPAGATION AND CULTURE.

Part the roots in autumn, ſoon after the ſtalks decay, or in the ſpring, before the roots begin to ſhoot. It loves a moiſt ſoil, and a ſhady ſituation.

DESCRIPTION, *&c.*

This is an annual plant, having the habit of Hypericum or Corchorus. Stem erect. Leaves alternate, ovate-lanceolate, bluntly ſerrate. Peduncles lateral, one-flowered; upright when in flower, bent down when in fruit. Flowers white. Eaſily diſtinguiſhed by its ciliate ſtipules[h].

Jacquin ſays, it ſcarcely ever exceeds a foot in height. Stems round, branched, herbaceous. Leaves acute, ſmooth, petioled. Stipules lanceolate, acuminate, with briſtly ciliæ round the edges. Peduncles ſhorter by half than the leaves. The flowers have no ſcent.

According to Browne, this beautiful little plant riſes generally in an oblique direction, and ſeldom ſhoots above ten or twelve inches from the root; the ſtalk is delicate, ſmooth and round, caſting a few ſlender branches on every ſide, without any certain order. Leaves ſmall, oblong, ſmooth on the upper ſide, very lightly crenated, and diſpoſed in an alternate but irregular order: they are on ſhort foot-ſtalks, and adorned with remarkably ciliated ears or ſtipules on each ſide, at their inſertions.

Native of St. Domingo, Martinico, Jamaica, Surinam, and Guiana.

Leaves ſpatulate obtuſe ciliate undivided, ſtem proſtrate, pedicels axillary one-flowered.

DESCRIPTIONS, *&c.*

1. Panicle very much branched many-flowered, or branched a little with few flowers. Petals unſpotted or ſpotted and that conſtantly [i].

There are numerous varieties of this ſpecies; Barrelier has figured five: they all approach by their fleſhy, oblong ſpatulate leaves, ciliated by little teeth turned towards the point, moſtly whitiſh on the upper ſurface by ſcales in ſhape of little creſcents, as Scopoli has remarked. The petals are white, oblong and blunt, often ſtained with yellow at the baſe [k].

Scopoli obſerves that there are white ſcales (ſcutella) placed at the edges of the leaves, which are waxen, roundiſh, on very ſhort pedicels, which are concealed within little pores: that the younger ſcales have this little pore in their middle, and that there is one of theſe at each notch of the leaf: that the younger leaves are oval, the older ones oblong and lanceolate, with the edges bent back: the ſtem more or leſs leafy and panicled: the petals white variegated with many little red dots: and the capſule quite two-celled, with a receptacle in each cell having more than five ſeeds adhering to it.—Gærtner deſcribes the capſule as ſubglobular, covered with the calyx which is looſe from it; the partition membranaceous, thickened in the middle, deeply divided when mature, having no receptacle except the thickened part of the partition, to which the ſeeds are faſtened: theſe are ovate-acuminate, angular, rugged with very minute pointed dots, and of a blackiſh colour.

This author remarks that Saxifraga, Heuchera and Hydrangea do not differ eſſentially in the parts of fructification; and that Heuchera might be denominated a pentandrous, Hydrangea an arboreous Saxifrage.

Varieties α and β are certainly not diſtinct. γ may poſſibly be a different ſpecies, the ſtem being conſtantly more compound, and the petals unſpotted. Haller's plant (n. 977.) ſeems however to be different from the norwegian figured in Flora danica, t. 241. The petals in the former being linear and ſubciliate at the baſe; but in the latter roundiſh [l].

Mr. Miller has made three ſpecies out of theſe varieties.] The roots of all are perennial and fibrous, and the leaves are gathered into circular heads, embracing each other at the baſe, like the common Houſeleek. Thoſe of his n. 2. (variety α) are tongue-ſhaped, about two inches long, and a quarter of an inch broad. Stem about a foot high, purpliſh, a little hairy, and ſending out ſeveral horizontal branches the whole length. Flowers in ſmall cluſters at the end of the branches; white with ſeveral red ſpots on the inſide.

In n. 3. (variety β) the leaves are not more than half an inch long, and wedge-ſhaped. Stem ſeldom more than ſix inches high, in the wild ſtate, but in gardens often more than a foot, having ſmall leaves ſitting cloſe to it the whole length. Flowers in looſe panicles at the top of the ſtem, white ſpotted with red.

In n. 4. (which ſeems to be the ſame with variety γ) the leaves are two inches long, and half an inch broad and tongue-ſhaped. Stem a foot and half high, branching out near the ground, and forming a pyramid to the top. Petals white, wedge-ſhaped.

When theſe plants are ſtrong, they produce very large pyramids of flowers, which make a fine appearance; and being kept in the ſhade, and ſcreened from wind and rain, will continue in beauty a conſiderable time. They all flower in june. The two firſt are natives of the Alps, and the third of the Pyrenees.

[It appears from Parkinſon that the Pyramidal Saxifrage was cultivated here in 1629 [m]. This author calls it *Navelwort*, and one variety *Princes Feather*.

2. This differs from the preceding in having a racemoſe leafy ſtem, and a ſmooth calyx [n]. Linneus had made it a variety of that, and it probably is ſo. Native of the Alps.

3. This has the appearance of being a hybridous or male plant, allied to S. Cotyledon, yet diſtinct from it. Root-leaves ciliate-villoſe towards the baſe. Stem firmer, ſimple and more abundant in leaves, alſo more viſcid. Racemes alternate, ſhort. Flowers four times as large; with the petals lanceolate, long, ſaffron-coloured [o].

Though in the general form of its foliage, it is as nearly related to S. Cotyledon as moſt of the varieties, yet from four of them it is perfectly diſtinct, having inſtead of the ſerrate cartilaginous edge, only fine ſoft hairs, more eſpecially towards the baſe: towards the extremity there is ſome appearance of little teeth, but widely differing from thoſe of the others. The whole plant is covered with viſcid hairs; the ſtalk, about a

[i] Linn. ſyſt. [k] Villars. [l] Willdenow. [m] Hort. kew. [n] Willdenow. [o] Linn. ſpec.

Digitized by Google

ſoot high, is much branched; but the great peculiarity of this plant conſiſts in its flowers, the petals being long, narrow and pointed, of a deeper colour when they firſt ripen, but gradually changing from ſaffron to a pale yellow; the beauty of the flowers is heightened by a glandular ſubſtance in the centre of each, which when the flower expands, is of a bright purple colour [p].

Notwithſtanding theſe peculiarities, Haller ſays it ſufficiently reſembles S. Cotyledon; and Villars doubts whether it be really a diſtinct ſpecies.

Native of the mountains of Switzerland, Carniola and Italy. Mr. Curtis raiſed it from ſeed ſent him by the much to be lamented Mr. Daval, of Orbe in Switzerland.]

4. Root perennial, fibrous. Leaves ſeven or eight inches long, and two broad towards the top, of a deep green and thick conſiſtence, ſpreading near the ground. Stem a foot and half high, branching at top in form of a panicle, and ſuſtaining very ſmall herbaceous flowers, collected into little heads.

[The leaves on the upper ſurface and at the edge, are covered, as is alſo the ſtem, with ſhort, jointed hairs [q].

Native of North America. Cultivated in 1732, by James Sherard, M.D. It flowers in may and june [r].

5. This reſembles the preceding ſo much, that it ſeems at firſt ſight hardly to be different, but it is really diſtinct in its manner of flowering. The leaves are ſmooth on both ſides, very finely ciliate at the edge, with ſhort jointed hairs. Stem a foot high, quite ſimple, round, pubeſcent. Peduncles four or ſix together alternately by intervals, and ſupported by a lanceolate bracte. The upper flower ſubſeſſile and more cluſtered.—Native of the Carpathian mountains [s].

6. Leaves cluſtered next the ground, free, elliptic, hirſute, not thick, commonly blunt at the end, ſeldom three-toothed. Stem three inches high, with ſmall leaves or ligules ſcattered over it, commonly few-flowered; but ſometimes it has only one flower. Petals greeniſh white marked with lines [t].

It is a very ſmall plant, and its ſhort, blunt, villoſe, entire leaves (ſeldom three-toothed) reſemble thoſe of *Androſace villoſa*, whence Linneus's trivial name. Stems from one to three inches high, terminated by one or two unequal flowers. Petals ſmall and whitiſh. Fruit large in proportion to the plant [u].

S. pyrenaica of Scopoli which Jacquin, Reichard and Willdenow refer to this ſpecies, is referred by Villars to S. cæſpitoſa: from which Scopoli affirms it to be totally different. He deſcribes the leaves as being never trifid, and yet they are all ſo in his figure.

Native of Switzerland, Auſtria, Dauphiné, Piedmont, Siberia.

7. Root creeping, long, branched, covered with brown ſcales. Tufts very cloſe, formed of hard, oblong, acute leaves, grooved along the middle, bluntly lanceolate, bent downwards at the end, glaucous, ciliated next the petiole, irregularly dotted underneath when examined with a magnifier. Stem naked (except a few ligules) four inches high, bearing one, three or five milk-white flowers, with round petals marked with lines [x].

Villars remarks, that it reſembles *Diapenſia helvetica* in its habit; that the leaves are whitiſh, entire, with ſome pores on the upper ſurface, that they are heaped one upon another, and form ſolid tufts; that the little ſtems are one or two inches high, ſimple, ſtraight, villoſe, having two or three narrower leaves at bottom, and two or three biggiſh white flowers at top.

There is a variety from the high mountains of Italy, the ſtem of which is double the ſize of the other, hirſute and viſcid. Calyxes large, hirſute. Leaves four times as large, ſpreading, nearly as in S. Cotyledon, diſtinguiſhable by the dots punched through them [y].

[p] Curtis. [q] Willdenow. [r] Hort. kew. [s] Willdenow. [t] Haller. [u] Villars. [x] Haller. [y] Linn. mant.

Native of the Alps and Pyrenees, Auſtria and Monte Baldo.

8. This has the appearance of a ſmall Sedum. Leaves like thoſe of Juniper, cloſely imbricate, acute, keeled, ſmooth. Stem ſcarcely a finger's length, ruſeſcent-hiſpid or glutinous, with three or four alternate, linear leaflets. Flowers milk-white with pale lines.

Vandelli has a variety from Italy with five-flowered ſtems and faſtigiate flowers [z]: and to this belongs Haller's n. 983. which he ſays has three, four and even ſix flowers, whereas Linneus's *burſeriana*, deſcribed by Wulfen in Jacquin's *miſcellanea*, has only one flower.

Native of Carinthia.

9. Stem very much branched, filiform, depreſſed. Leaves aggregate, linear, even. Peduncle often one-flowered, more ſeldom two or three-flowered. Flower ſuperior [a].

This is deſcribed at length by Wulfen in the ſecond volume of Jacquin's *miſcellanea*. He found it in Carinthia in 1768; but Seguier obſerved it forty years before in the mountains near Trent, afterwards Haller in ſeveral places of Switzerland and the Valais, and Scopoli in Carniola, both of them ſuſpecting it to be Seguier's plant, and the latter referring it to the *S. aizoides*, though Linneus had given Seguier's name to his *ſedoides* without heſitation.

It varies much, according to Wulfen, in its habit, height and leaves.

10. This approaches to the next ſpecies, but the flowers are only one-fourth of the ſize, the calyx is mucronate, the germ inferior and glandular-hairy.—Native of the mountains of Carinthia [b].

11. Leaves ſerrate, ciliate at the baſe, with the ſerratures often calloſe at the tip. Root-leaves in a ring: ſtem-leaves five or ſix, alternate, tender. Stem pubeſcent. Flowers one or few. Petals pale yellow with tawney or orange ſpots [c].

Native of the Alps and Pyrenees, Auſtria, Carniola, Dauphiné, Piedmont. Introduced in 1775, by the Doctors Pitcairn and Fothergill [d].

12. Runners oblong imbricate in cluſters. Leaves flat, mucronate-ſpined, ſpiny-ciliate. Stem high, almoſt naked, with a few very ſmall mucronate leaves even at the edge. Panicle ſmall.

Native of Siberia [e].

13. Roots perennial, long, fibrous, crowned with flat ſtellate tufts of obovate-cuneiform leaves, which are hairy above, eſpecially about the edge, paler and ſmooth ſometimes purple beneath, pointed and groſsly ſerrate towards the end. From each tuft ariſes one naked ſtem, rooting a little at the baſe, from two to ſix inches high, erect, round, clothed with ſcattered divaricating hairs, divided at top into a ſort of corymb or panicle of from three to ſeven or nine flowers, each on a ſeparate pedicel, having a lanceolate entire or ſometimes trifid bracte at the baſe. Calyx reflexed. Petals ovate, clawed, three-nerved, white with two yellow tranſverſe ſpots near the baſe. Stamens connected at the baſe, all nearly equal: anthers purple. Germ quite ſuperior, ovate, purple. Capſule membranaceous, nerved, ſmooth, green with a purple ring near the baſe. Seeds rugged with raiſed tubercled longitudinal lines [f].

Native of the mountains of Spitzbergen, Lapland, Switzerland, Styria, Dauphiné, Piedmont, Siberia, and Britain. In our northern counties, Weſtmoreland, Cumberland, Lancaſhire, Yorkſhire; in Wales, and in Scotland, abundantly, on the black turfy margins of rills, on the north ſides of the mountains, towards their ſummits; where it flowers in june and july [g]. Alſo in Ireland, in moiſt places about Slieve Cavelagh, one of Mourne mountains.

14. Root ſuperficial, black, ſcaly with the relics of dead leaves, the thickneſs of a finger or thumb, round, ſending down filiform fibres from the lower ſurface. Stems from the axils of the leaves of the year pre-

[z] Linn. ſpec. and ſyſt. [a] Linn. ſyſt. [b] Willdenow. [c] Linn. mant. [d] Hort. kew. [e] Linn. ſpec. [f] Smith brit. Engl. bot. Woodw. Mſs. [g] Engl. bot.

ceding

Digitized by Google

ceding at the tops of the roots alternate, very ſhort, almoſt upright, covered with the ſheaths of the leaves, quite ſimple, but branched in autumn. Leaves three or four, alternate, ſpreading very much, obovate-oblong, crenulate, ſubretuſe, very ſmooth, veined, a ſpan long, flat, coriaceous. Petioles ſhorter by half than the leaves, roundiſh, channelled, ſmooth, with a wide membrane at the baſe, of an ovate form, embracing, and in the winter ſeaſon ſerving for a gem. Scape or peduncle terminating, ſolitary, erect, a ſpan high, the thickneſs of the little finger, roundiſh, very ſmooth, purpliſh, almoſt naked, many-flowered. Panicle contracted, naked, blood-red, compoſed of pedate racemes. Flowers inferior, drooping, pedicelled. Pedicels ſhort, round, rugged. Calyx ſhorter by half than the corolla, angular, ſhining, with the receptacle of the flower yellow, five-cleft to the middle; ſegments oblong, erect, quite entire, rounded at the top, ſomewhat wrinkled, green. Corolla funnel-form, purple: petals incumbent, inſerted into the middle of the calyx, wedge-ſhaped, erect, very blunt. Filaments ſhorter by half than the corolla, alternately leſs, inſerted into the calyx with the petals. Anthers erect, cordate, blunt. Piſtil the length of the corolla, yellowiſh green. Germs two, half round, ovate, ſmooth: ſtyles compreſſed, linear: ſtigmas kidney-ſhaped, blunt.

The root is white within, and very ſtiptic or aſtringent when chewed. The ſtem changes every year into root; that which flowers one year loſing its leaves during the winter, turning to the ground, becoming black, and putting forth fibres.

After the plant has flowered, the ſtem puts forth branches from the axils of the leaves, which have the panicle of flowers for the next year included in their gems. When the flowers fade they turn blue [h].

Mr. Curtis remarks, juſtly enough, that the term *grandifolia* would have been more applicable to this ſpecies than *craſſifolia*, for it is not ſo much diſtinguiſhed for the thickneſs as the largeneſs of its leaves; which are almoſt equal in ſize to thoſe of our broad-leaved Dock; they are red on the under, and of a fine ſhining green on their upper ſurface, and may be ranked among the more handſome kinds of foliage. The flowering ſtems, according to the richneſs and moiſture of the ſoil in which they are planted, riſe from one to two or even three feet high; at top ſupporting a large bunch of purple pendulous flowers, expanding in april and may, and if the ſeaſon prove favourable, making a fine appearance [i].

Native of Siberia, whence living plants were ſent to Linneus in 1760, by David de Gorter, phyſician to the Empreſs of Ruſſia [k]. It was introduced here in 1765, by Daniel Charles Solander, LL. D. [l]

β. There is another Saxifrage in our gardens, exceedingly like this in appearance, but differing, in producing larger bunches of flowers, and in having larger, rounder and more heart-ſhaped leaves. In the Kew catalogue this is ſet down as a variety of the *craſſifolia*. Mr. Curtis is inclined to conſider it as a ſpecies under the name of *cordifolia*. He remarks, that the parts of fructification in *craſſifolia* are apt to be preternaturally increaſed [m].

15. Root perennial, black, ſending down long fibres into the black moiſt ground. Leaves radical, ſpreading, fleſhy, lengthened out at the baſe, dark green above, purpliſh beneath, eſpecially near the edges and tips, hairy about the margin. Stem for the moſt part ſolitary, erect, three or four inches high, ſimple, leafleſs, round, clothed in the upper part with fine hairs tipped with viſcid moiſture, terminating in a cluſter of ſeveral flowers, on ſhort, ſometimes branched flower-ſtalks, the lower moſt often accompanied by a ſimple entire bracte. Teeth of the calyx fleſhy, purple. Petals ovate, obtuſe, white ſpotted with pale green, frequently purpliſh. Piſtils white or purpliſh [n].

This ſpecies has the habit of *S. ſtellaris*, but the leaves are wider and more fleſhy, reddiſh beneath; the petals are ſpotted with green; the piſtils are purpliſh; and eſpecially the germ is half inferior, not ſuperior, as in that [o].

Ray's figure is better than Lightfoot's, but neither is good: A luxuriant branched ſpecimen is repreſented in Flora Danica [p].

Scarcely any plant is ſubject to more variations, in appearance as well as ſize. Sometimes it is exceedingly ſmall, with heart-ſhaped leaves, flowers collected into a ſingle head, and a ſtrap-ſhaped leaf at the baſe. Sometimes it produces only a ſingle flower on a ſtalk, and ſometimes two of theſe riſe from one root. At other times it bears a number of flowers at the top of the ſtalk, on fruitſtalks, forming an umbel, and ſometimes it appears twice as large, with a ſpike compoſed of ſmaller ones, as figured by Ray [q].

Native of Britain, Spitzbergen, Lapland, Virginia, and Canada.—This is the moſt alpine of our Britiſh Saxifrages, and is found only on the ſummits of the higheſt mountains in Scotland and Wales, as Ben Lomond, Snowdon, &c. Flowering in auguſt [r]. J. W. Griffith, Eſq. of Garn, near Denbigh, has ſeen the ſame plant flower thrice in one ſummer [s].

16. From a fibrous root proceed tufts of leaves, which are hirſute, not marked with lines, dark green, wedge-ſhaped, three or five-lobed, with the middle lobe larger and bluntiſh. From the centre of each tuft iſſues one flower, ſeldom two or three; they are ſeſſile, and the petals are elliptic and pure white.

Native of the Piedmont alps on moiſt moſſy rocks. Found by Bellardi [t].

17. Native of the higheſt alps of Dauria, under the ſnow.

18. The ſtature of the plant is altogether that of *Heuchera*. Root-leaves petioled, cordate-ſuborbicular, hairy, crenate, with blunt lobules, oleraceous, having white veins on the upper ſurface, beneath liver-coloured. Petioles roundiſh, longer than the leaf. Stipules none. Stem herbaceous, round, a foot and half high, almoſt leafleſs, pubeſcent, as the whole herb is, with hairs ſtanding out; the whole raceme compound, the partial racemes drooping at the end before they flower. Branched runners proceed in abundance from the axils of the root-leaves, terminating in rooting offsets. Three of the petals are ſmaller, whitiſh ſtained with red; two larger, white. Nectary yellow. Stamens white, thicker above, the length of the ſmaller petals. Styles the ſame length. Two of the ſtamens, when they have ejected their pollen, turn back behind the corolla [u]. Capſule rounded-ovate, two-beaked, one-celled, two-valved, ſmall, faſtened to the calyx only by the baſe [x].

Its round variegated leaves, and ſtrawberry-like runners, with the uncommon magnitude of the two lower pendant petals, joined to the very conſpicuous glandular nectary, in the centre of the flower, half ſurrounding the germ, render this ſpecies ſtrikingly diſtinct [y].

Mr. Curtis remarks, that it differs ſo widely from the other Saxifrages, as to create a doubt in the minds of ſome, whether it ought not to be conſidered as a diſtinct genus. Thunberg is of opinion, that it can ſcarcely conſtitute a new genus, although the petals be unequal.

Native of China and Japan. Introduced in 1771, by Benjamin Torin, Eſq. It flowers in june and july [z]. Jacquin ſays (in 1781) that he had this elegant plant many years ſince from Spielmann. The younger Linneus ſeems to have had it from our Gordon of Mile-end.

Loureiro has a ſpecies, which he names *S. chinenſis*. He deſcribes it as an herbaceous ſtemleſs plant. Leaves aggregate, cordate-roundiſh, fleſhy, interruptedly crenate, hairy, reddiſh beneath, on long petioles. Scape naked, ſix inches high. Panicle diffuſed. Corolla white, wheel-ſhaped, five-petalled, the two outer petals double the ſize of the others. Capſule two-beaked, two-celled.—Notwithſtanding the two cells, it agrees in all other circumſtances with *Saxifraga*;

and although it be not ſarmentoſe, yet it approaches very nearly to Linneus's *S. ſarmentoſa*.—Native of China, about Canton [a].

The Loo-Foo Yee (Tyger-ear) which the Chineſe plant in their artificial rock-work, is probably one of theſe. They alſo uſe the juice of the bruiſed leaves to eaſe the tooth-ach. The Chineſe name of Loureiro's plant is *Ho agi ſſao*.

19. Leaves roundiſh, gaſh-toothed ſo as to be almoſt lobed, without any cartilaginous border, by no means retuſe, but the teeth acute. Petioles even, three times as long as the leaves, gradually widening into the leaf. Flowers ſmaller than in *S. Geum*, almoſt inferior.

Native of Siberia [b].—Mr. Miller has miſtaken this for the next ſpecies.

20. Leaves all radical, aggregate in tufts, ſpreading, running down into the petiole, even and quite ſmooth, often purple beneath. Scape a ſpan high, erect, red, hairy, many-flowered, with a few ſmall alternate bractes. Flowers upright. Calyx finally reflexed. Petals obovate-lanceolate, white or fleſh-coloured, moſt beautifully dotted with yellow and dark red. Germ altogether ſuperior, roſe-coloured. Capſule ventricoſe, tipped with purple [c].

Native of Ireland and England. Found in the former on a mountain called the Mangerton, two miles from Killarney, by Dr. Molyneux; on the mountains near Sligo, by Mr. Lhwyd; on Croagh Patrick in the county of Mayo, by A. B. Lambert, Eſq.: in the latter, in Thorp Arch woods, near Weatherby, Yorkſhire, by Sir T. Frankland and Dr. White; and between Arncliffe and Horton in Craven, Yorkſhire, by Mr. W. Bingley. It flowers in june and july.

Mr. Hudſon omitted this plant in his Flora Anglica. It was long cultivated in England before it was known to be indigenous; and was a favourite for the elegance of the flowers, on which account it was named None-ſo-pretty; as alſo for its thriving in London better than moſt plants, whence it had the name of London Pride.]

21. Leaves thick, kidney-ſhaped, crenate, deep green above, pale green beneath, on long thick hairy foot-ſtalks. Corolla white marked with red ſpots. Stamens longer than the petals. It flowers in june.

[Linneus remarks both of this and the preceding, that they are too nearly allied to *S. Geum*. That however has the leaves by no means cordate at the baſe, with angular notches, and ciliate-villoſe petioles: the flowers are inferior. This has the leaves oval, not kidney-ſhaped, and the calyx reflex.—Native of the Pyrenees.

22. Leaves in ſpreading tufts, producing other little tufts, thick, ſolid, white and cartilaginous at the edge, in form nearly reſembling thoſe of *Leucanthemum*, but more obtuſe, ſlightly and bluntly crenate all round, red underneath and becoming more ſo as they advance in age. The upper ſurface, according to Scopoli, appears to have very minute ſilvery ſcales ſcattered over it, when it is examined with a microſcope; the lower part is gradually leſſened and converges into a flat petiole. Stem very brittle, a long ſpan in height. Panicle thin, with the flowers on long tender branched pedicels. Calyx reflexed. Petals white, thinly marked with yellow dots [d]; according to Scopoli, having a yellow ſpot at the claw.

This ſpecies very much reſembles *S. umbroſa*, the margin of the leaves however is not crenate, but very bluntly repand; the leaves alſo are much ſmaller [e].

Native of Switzerland, Styria, Dauphiné. Introduced in 1768, by Profeſſor de Sauſſure. It flowers here in may [f].

23. Diſtinct from the preceding ſpecies in having the leaves erect, not forming little roſes, ovate not wedge-ſhaped, ſubcordate at the baſe, and of the ſame width there as at the end, not ſo thick, but in drying corrugated at the margin, not red beneath, or ſcaly above, or running down into the petiole. Petioles villoſe. Petals dotted below the middle [g]. Calyx reflexed [h].

Native of the Alps of Europe. Cultivated here in 1629 [i].

24. Stems very long, trailing, either forming tufts or hanging down from the crevices of rocks, branched, leafy; the flowering branchlets erect [k]. The leaves, which are ovate and ſomewhat decurrent, grow in oppoſite pairs, alternately from each ſide of the ſtalk, giving it an appearance of being imbricated quadrangularly, and are all ciliate at the edges, of a glaucous green, frequently tinged with purple [l]; they are blunt, fleſhy, concave and keeled: the floral leaves are more remote. Flowers terminating, ſolitary, purple, large and handſome [m]. Calyx purpliſh, ciliate at the edges. Petals obovate, very obtuſe, nerved. Anthers purple. Germ half-inferior [n]. This beautiful plant inſinuates its roots into every crevice, and with its numerous trailing branches cloaths the rocks with a rich tapeſtry [o]; during the months of april and may. In gardens it flowers in february and march. As the flowers go off they incline to blue, and it is ſaid to vary with white flowers.

The plant is very liable to vary from ſituation: when it grows expoſed, the whole plant aſſumes a more compact appearance, the ſtalks are ſhorter, the leaves more cloſely imbricate, the flowers more numerous; in ſhady and more ſheltered ſituations, the ſtalks ſhoot to a greater length, the leaves are placed at longer intervals, aſſume a greener hue, and reſemble ſomewhat thoſe of wild Thyme; in ſuch ſituations few or no flowers are produced [p].

β. The leaves are more diſtinct and blunt: the little ſtem is only two inches high, and is terminated by one or two flowers of a beautiful red colour [q]. According to Allioni, the ſtem is only an inch high; the flower large of a beautiful roſe colour: the leaves hirſute, ciliate, ſeſſile, ovate, not reflexed, alternate even on the flowering branches. The whole plant is commonly very clammy.

γ. Calyx and corolla ſpread out. Stamens and ſtyles equal and higher than the flower. Anthers three-cornered, greeniſh yellow. Leaves acuminate, reflexed, ſmooth, ſometimes ciliate towards the baſe, cloſely imbricate on the ſtems, but conjugate and more apart on the flowering branches [r].

Native of Spitzbergen, Lapland, Britain, Switzerland, Dauphiné, Piedmont, Siberia; on alpine rocks: flowering in april. On Ingleborough and Pennigent; on Snowdon; on Ben Lomond, and other Scottiſh mountains; Iſles of Rum and Skye.

25. This has tufts of leaves forming dark roſes cloſe to the ground, and younger ſtalks, as it were gems, ſeſſile in the axils of the ciliate leaves. From the creeping ſtalk riſe up flowering-ſtalks, a long ſpan in height, weak, trifid or quadrifid. Leaves oblong, acute, rigidly ciliate at the edges. Flowers on long, naked, one-flowered branches, three or four in the whole, on the top of the plant. Calyx green with white edges. Petals duſky white with a yellow claw. Anthers ſcarlet. It reſembles *S. bryoides* very much [s].

Native of the mountains of Switzerland, Auſtria, Provence, Dauphiné, and Piedmont. Cultivated in 1748 by Mr. Miller [t]. Omitted in the later editions of his Dictionary.

26. Stems upright, about a ſpan high, round, ſimple, leafy, beſet thinly with browniſh crooked hairs, reddiſh beneath the flowers, branched at bottom; the branches ſhort and decumbent. Leaves bluntiſh, quite entire, ſmooth on both ſides, ſometimes ciliate at the edge with ſoft hairs. Flowers one or two (ſometimes three) large. Calyx reflexed, ſometimes edged with hairs. Petals obovate, nerved, appendicled at the baſe, of a golden colour, ſpotted with ſaffron up to the middle [u].

Mr. Woodward remarks, that the almoſt parallel nerves on the calyx and petals, clearly diſtinguiſh this

[a] Lour. cochinch. 281. ed. Willd. 345. [b] Linn. ſpec. [c] Smith, brit. & engl. bot. [d] Haller and Villars. [e] Linn. ſpec. [f] Hort. kew. [g] Scopoli. [h] Linn. ſyſt. [i] Hort. kew. [k] Smith. from the other ſpecies.—And Mr. Curtis, that it obviouſly differs from *autumnalis* in the ſuperior ſize and in the form of the petals, by the beautiful orange ſpots on the lower half of them, and by the two very ſingular pointed projections towards the baſe of each. It is indeed very different from all the European Saxifrages. It derives the trivial name, from its ſimilitude in foliage to *Valeriana celtica*, which is called *Hirculus* by ſome old authors [z].

Native of Lapland, Sweden, England, Germany, Switzerland, Piedmont, Siberia, in bogs: flowering in july and auguſt. Firſt found in England by Dr. Kingſtone, on Knutsford moor in Cheſhire, and ſhowed by him to Dr. Richardſon: and ſince by Mr. Howard, ſurgeon of Knutsford, Mr. Benjamin Haley, gardener to Mr. Egerton of Tatton-park, and others.

27. The roots creep very far. Root-leaves matted. Stems aggregate, decumbent at the baſe and branched, leafy, round, ſmoothiſh, the flowering extremities erect and panicled; the leaves on them much more ſcattered and larger. Leaves ſeſſile, blunt, edged with ſuch ſtrong and remote ciliæ, that they might almoſt be called dentated: theſe ciliæ are nevertheleſs ſometimes wanting, whence Linneus deſcribes his *S. aizoides* as having naked, not ciliate leaves. Even his own ſpecimen however has traces of them; and in fact the number and denſity of theſe ciliæ are very variable. Mr. Woodward remarks, that the leaves have ſometimes a few ciliæ, but are oftener naked. From the upper part of the ſtem ariſe many peduncles, each from the axil of a leaf, of various lengths, the lower ones longeſt, each clothed with two ſmall leaves, and generally bearing one flower. They often form a ſmall corymb, are extremely beautiful when cloſely examined, and thoſe that appear earlieſt are moſt deeply coloured. Calyx as long as the corolla, from upright ſpreading, even in the fruit. Petals tongue-ſhaped, nerveleſs, gold ſpotted with red. Germ depreſſed. Capſule ovate, half inferior [y].

Haller and Jacquin, and after them Lightfoot, ſuppoſe the Linnean *S. autumnalis* not to be ſpecifically diſtinct from this plant; and Linneus himſelf thought the hint worth noticing in his ſecond mantiſſa. His own herbarium has no ſpecimen to ſhow what he intended by *S. autumnalis*: probably he took up the plant from other authors. Dr. Stokes's conjecture is perhaps neareſt the truth, that Linneus's *S. autumnalis* is a ciliated variety of *S. Hirculus* [z].—Mr. Afzelius informed Dr. Withering, that *S. aizoides* and *autumnalis* of Linneus are the ſame plant: that when the leaves are fringed, it had been called by the latter, and when without fringe, by the former name [a].

Willdenow remarks, that the leaves are mucronate in *autumnalis*, which they are not in *aizoides*; and that the former varies with purple flowers.

Native of Lapland, Sweden, Norway, Britain, Switzerland, Carniola, Dauphiné, Sileſia, Piedmont. With us it is found in bogs and by rills, on moſt of the mountains in the north of England, and in Scotland; flowering in july and auguſt.]

28. Lower leaves almoſt round, reſembling thoſe of Golden Saxifrage (Chryſoſplenium,) on long foot-ſtalks, deeply divided, hairy and green above, pale beneath. Stems erect, about a foot high, channelled and hairy, with kidney-ſhaped leaves. The ſtem puts out a few ſlender foot-ſtalks from the upper part, which together with the ſtem itſelf are terminated by ſmall cluſters of flowers, white ſpotted with red. According to Haller, it is a cubit in height. Leaves hirſute; the lower on very long petioles, bluntly ſerrate; ſtem-leaves few, on ſhorter petioles, more ſharply ſerrate; at top dwindling into mere ſtraps. Flowers axillary, two or three on a peduncle: the outer dots on the petals red, but the inner ones yellow.—Stem pubeſcent with capitate villoſe hairs. Panicle dichotomous, looſe; with two narrow leaflets under each branch. Petals lanceolate, with ſhort truncate claws. Seeds ovate, up to eighty in a cell [b].

Of this numerous and beautiful genus, we know of none, ſays Mr. Curtis, whoſe flowers, in point of pretineſs, can vie with thoſe of the preſent ſpecies: they are marked with numerous fine dots, like thoſe of *umbroſa*, but in a ſuperior ſtyle of beauty, and appear to great advantage when viewed with a magnifier.

Native of Switzerland, Auſtria, Sileſia, Dauphiné, Piedmont. Cultivated by Gerarde, in 1597 [c].

29. Root compoſed of ſeveral little grains or knobs, attached to one main fibre, and throwing out ſmall fibres from their baſe. Stem erect, round, pubeſcent, leafy, ſomewhat viſcid, branched and panicled at top, of a brown or reddiſh hue, with which colour the leaves and calyx-teeth are alſo tinged, giving the whole herb a rich glowing appearance: theſe parts are alſo clothed with the ſame kind of hairs, eſpecially the calyx, which is very clammy to the touch. Leaves ſomewhat fleſhy, lobed and cut; thoſe next the root on long footſtalks; thoſe on the ſtem alternate, ſubſeſſile. Calyx erect. Petals obovate, much longer than the calyx, marked with three branched veins, white, undotted. Stamens all nearly equal. Stigmas blunt and pubeſcent [d].

Native of Europe, in dry paſtures and on banks, where the ſoil is gravelly. In Britain it is not very common, but where it does occur it is found in plenty: flowering in may, and ſeeding in june.—As a medicine it is of no efficacy.

β. It varies with double flowers, and in this ſtate is cultivated. I preſume that this is the variety, which Mr. Miller ſays] was found wild by Mr. Joſeph Blind, gardener at Barnes, who tranſplanted it into his garden, and afterwards diſtributed it to ſeveral curious perſons; ſince which time it has become a very common plant in moſt gardens near London, where it is commonly planted in pots to adorn court-yards in the ſpring, and is very ornamental at that ſeaſon in the borders of the flower-garden.

[30. This is rather a variety of the preceding than a diſtinct ſpecies, according to Seguier. The germ is inferior. This character is what principally diſtinguiſhes it from *S. cernua*. Other characters are not to be depended upon [e].

Native of Italy, in ſhady rocky paſtures; and of Norway. The Biſhop of Drontheim gathered it in 1762 and 1767 at Tromſoen in Norland, &c.; and Koenig in Iſland.

31. Root a ſmall ſcaly bulb, throwing out branched black fibres. Stem four or five inches, or a ſpan high, erect, round, leafy, moſtly ſmooth, generally ſimple and one-flowered, ſometimes branched. Leaves alternate, kidney-ſhaped, lobed in a palmate manner, a little ſucculent, ſmoothiſh; the upper ones undivided and ſeſſile, bearing in their axils little purple ſcaly bulbs, which falling to the ground become new plants. Flower terminating, ſolitary, white, nodding: ſegments of the calyx elliptical, erect, clothed with glandular hairs: petals clawed, retuſe and ſubemarginate, three-nerved, the nerves united above the baſe, branched and diſappearing before they reach the top. Germ entirely ſuperior.

Native of the mountains of Lapland. Mr. Dickſon firſt detected it on the ſummit of Ben Lawers in Scotland. It flowers in july or auguſt.—Figure 390 of Flora Danica ſeems to repreſent this plant: figure 22 having acute petals, and always a ſimple ſtem. This may perhaps be another ſpecies [f].

32. Root fibrous. Stem for the moſt part ſolitary, two inches high, erect, ſimple, two-flowered, ſometimes five-flowered. Leaves on long petioles, alternate, ſomewhat kidney-ſhaped, palmate, three or five-lobed, ſmooth, the upper ones ſpatulate and undivided. Flowers erect, ſmall, white. Calyx hairy-viſcid at the baſe. Petals acute, one-nerved. Germ ovate, half-inferior.

Native of the Lapland mountains; Finmark and Norland; Siberia; Scotland, found on Ben Nevis, by rills and in the wet fiſſures of rocks, by Dr. Townſon, flowering in june and july [g]. Linneus marks it as annual, Smith as perennial.

[z] Curtis. [y] Smith, brit. & engl. bot. Woodw. Mſs. [x] Eng. bot. [a] Botan. arr. 405. [b] Scopoli. [c] Hort. kew. [d] Smith, brit. & engl. bot. [e] Gunner. [f] Smith, brit. & engl. bot. [g] Smith, brit.

Digitized by Google

33. Root ſtoloniferous. Stem half a foot high, pubeſcent, viſcid. Leaves five-lobed, with the lobes acutely trifid, the two ſide lobes ſo united, that they appear to be three-lobed, with the ſide-lobes five-toothed: the younger leaves are often cordate, five or ſeven-lobed, with the lobes quite entire and equal. There is ſeldom more than one ſtem-leaf, and ſometimes there is none: when there is one only, it is three-lobed, either with the middle lobe quite entire and the ſide-lobes one-toothed, or with all the lobes two-toothed or three-toothed: the middle ſtem-leaf, when there are two, is petioled, and the upper one ſeſſile. Peduncles axillary, alternate, commonly three-flowered, ſometimes but ſeldom five-flowered. Pedicels alternate, ſeparated by awl-ſhaped leaves; the lower flower has two others and opens firſt, then the middle one, and laſtly that at the end. Calyxes pitcher-ſhaped, almoſt as in the Roſe, with long acute ſegments. Petals white, lanceolate, bluntiſh, the ſame ſize as in *S. ceſpitoſa*, *hypnoides*, and *granulata*. Filaments ſtiffiſh, the length of the calyx. Capſule very much forked, with diverging points. After flowering-time the calyxes ſwell very much, and their ſegments are ſo enlarged, that they emulate in a manner thoſe of Roſes.

Native of the Pyrenees, by rills and on ſhady rocks [h]: alſo of Siberia. Introduced in 1770, by Monſ. Richard. It flowers in april and may [i].

34. Root-leaves palmate and five-parted, with ovate-lanceolate lobes, and petioled. Stems aſcending, filiform, with two or three linear acute undivided leaves. Flowers at the top from three to five, peduncled. Runners before they put out leaves hirſute.—Native of the mountains of Provence [k].

35. Radicles capillary. Root-leaves petioled, ſeven-lobed: lobes ovate, with hairs thinly ſcattered over them: petioles hirſute. Stem aſcending, half a foot high, weak, having two or three ſeſſile palmate leaves on it. Peduncles terminating and lateral, very long, filiform, bifid, naked. Flower biggiſh, white, inferior.—Native of Siberia [l].

36. This is an annual plant, very diſtinct from *S. geranioides* and *adſcendens* in the form of the leaves, peduncles and petals: ſo it is alſo from *S. tridactilites* and *petræa*, although there be a ſort of agreement in the form of the leaves and petals.—Native of the mountains of Carinthia [m].

37. Root annual, ſmall, entirely fibrous. The whole herb is ſucculent, pubeſcent with projecting hairs which are clammy from the globules which terminate them, and turning red after flowering. Stem erect, round, leafy, ſomewhat flexuoſe, dichotomous. Leaves palmate in three ſegments, or pedate in five, tapering down into a wedge-ſhaped baſe, their margin entire, their ſubſtance tumid and fleſhy; the uppermoſt lanceolate, undivided, and ſeſſile. Panicle erect, with ſmall leaves at the forks. Flowers ſmall, white, on ſolitary peduncles. Calyx urn-ſhaped, with ſmall teeth. Petals obovate, one-nerved, ſcarcely exceeding the calyx. Germ quite inferior. Styles greatly divaricated.

Common in moſt parts of Europe, on walls, thatched roofs, and in dry barren places, flowering in april and may. When it grows in ſhady places, it is green, more ſlender, and longer lived. In very dry ſituations, the ſtem is ſometimes unbranched, and all the leaves entire.

This little herb has been taken for the *Paronychia* of Dioſcorides, which was uſed to cure whitlows; and hence its Engliſh name of Whitlow-graſs; to diſtinguiſh it from *Draba verna*, which is alſo ſo called, the epithet *rue-leaved* is added to this [n].

38. This is alſo an annual plant, very nearly allied to the preceding, and viſcid as that is; but the ſtem is very much branched, the leaves wide palmate three-parted and cut, the corolla three times as large [o]. Willich ſays, it is perennial, that it grows in tufts, compoſed of palmate five-cleft leaves, not very cloſe, expanding more when the plant is in flower, and even reflexed, that the flowering-ſtem puts out numerous barren branches at bottom, the lower leaves of which reſemble thoſe in the tufts, but the others are three-toothed and widely petioled, that it is hairy and viſcid, branched again at top, with a ſeſſile leaf under each branch which is commonly trifid, but ſometimes though rarely ſimple, that the calyx is half-five-cleft cloſely ſurrounding the germ, that the petals are milk white ovate entire marked half way with green lines, and as large as in *Sax. granulata*.

According to Retzius, the *petræa* of Gunner and the Flora Danica is quite a different plant from this of Linneus, Willich and Gouan. The *petræa* of the latter is referred by Willdenow to Linneus's *adſcendens*, together with Pona's *S. alba petræa*; but ſurely Pona's plant is the ſame with Linneus's *petræa*.

Native of the mountains of Lapland, Norway, Switzerland, Savoy, Carinthia, Dauphiné.—Cultivated in 1748, by Mr. Miller [p]; but omitted in the later editions of his Dictionary. It flowers in april and may.

39. This is a viſcid plant, leafy all over, with the flowering ſtems only from the top, and not as in *petræa*, to which it is very nearly allied, branched very much every way into a bundle [q].

Vahl remarks, that there are always runners in this ſpecies, which he has never obſerved in *petræa*, that it is alſo much ſtouter, with a greater abundance of larger flowers, which are moſt commonly on ſhorter peduncles.

Native of the Alps and Pyrenees, monte Baldo, the Hartz foreſt, &c.

40. This has the habit of *ceſpitoſa*, but the leaves are much more ſlender, almoſt all of them undivided, triple-nerved beyond the middle. Petals yellowiſh, triple-nerved. Germ inferior. The herb is ſweet-ſmelling and viſcid [r].—Haller remarks that the roots have a pleaſant aromatic flavour; that the leaves are particularly tender, like Chineſe ſilk paper; the ſtem three inches high or a little more, hirſute, bearing two or three flowers; the petals white with a tinge of yellow.

Native of Switzerland, the Pyrenees, Carniola, &c. Its place in England, (mountains above Ambleſide, Weſtmoreland,) reſts on the authority of Dr. Withering.

41. Root in tufts. Stem two inches high, erect, not very leafy, round, hairy. Root-leaves heaped, numerous, ciliate, blunt; ſtem-leaves alternate, commonly undivided, but ſometimes three-parted. Flowers terminating, peduncled, erect, yellowiſh. Calyx hemiſpherical, hairy-viſcid, with the ſegments blunt and denudated. Petals obovate, quite entire, triple-nerved. Capſule almoſt inferior [s].

In Linneus's mantiſſa it is ſaid to be a ſmooth plant, with the upper branchlets viſcid; the corolla white, drying yellow, and marked with lines.

Scopoli deſcribes it as truly tufted, with a ſhort ſtem, an inch or a little more in height, having a few one-flowered peduncles at the top, and a trifid leaf at the baſe of the lower peduncle. The lower leaves are ſemitrifid, with equal ciliate blunt ſegments. Segments of the calyx oval. Petals yellow, with three lines, of which the ſide ones being united at top and bottom incloſe an oval ſpace.

Native of Sweden, Norway, Switzerland, Auſtria, Carniola, Sileſia, Dauphiné, Piedmont.—Found on alpine rocks above lake Idwell in Caernarvonſhire, Wales, by J. W. Griffith, Eſq. flowering in june.

β. Willdenow, following Jacquin, makes this a diſtinct ſpecies from *ceſpitoſa*, although it reſembles that very much; on account of the greater ſlenderneſs of the leaves, the filiform ſtem, and the ſmallneſs of the flower. It is deſcribed at length by Wulfen in Jacquin's miſcellanea.—Native of the mountains of Carniola and Switzerland, alſo of the Pyrenees.

γ. Stems ſeveral, ſcarcely exceeding two inches in height, thickiſh, covered with many trifid leaves. Flow-

[h] Gouan. [i] Hort. kew. [k] Linn. amoen. [l] Linn. ſpec. [m] Willdenow. [n] Smith, brit. engl. bot. Withering. [o] Linn. ſpec. [p] Hort. kew. [q] Linn. mant. [r] Smith, brit. [s] Idem.

ering-

ering-ſtems ſhort, with one or two leaves, and three or four ſmall whitiſh flowers on them.—Native of Groenland; found in Mackel Cow bay, flowering in july, by Francis Soldan, a ſurgeon, and preſented by him to Dr. James Sherard, who cultivated it in his garden at Eltham[t]. It is alſo a native of Norway.

δ. Root-leaves forming a tuft, from a narrow baſe widening into a triangle, and deeply cut into three linear lobes, which are three-toothed or ſometimes but rarely four-toothed. The ſtem has one leaf on it about the middle, divided into five lobes; the flowers on the top form a ſort of umbel, and there is a five-cleft or three-cleft leaf at the origin of the peduncles. Pedicels one-flowered, naked, three times as long as the flowers. Calyx deeply cut into lanceolate ſegments. Corolla ſpreading: petals white, twice as long as the calyx. Filaments with their anthers greeniſh-yellow, not higher than the calyx. The whole plant is viſcid and hirſute. It varies with leaves not deeply trifid, but rather five-lobed, the middle lobe often bifid or trifid, and the white petals roſe-coloured at the claws.—Native of the Piedmont Alps[u].

42. Root-leaves numerous, in tufts, from the centre of which ariſes a ſimple erect flowering-ſtem, a hand high, round, hairy, ſurrounded at the baſe with ſeveral nearly upright, ſhortiſh, leafy ſhoots or branches. All the leaves are palmate, narrowed and lengthened out at their baſe, clothed with long white woolly ſcattered hairs; the radical ones, as well as one or two on the lower part of the ſtem, are in five (rarely ſeven) ſegments; the others on the ſtem and thoſe on the ſide ſhoots in three: all the ſegments are inclined to be elliptical, not linear. Panicle erect, terminating, viſcid, not very ſpreading, compoſed of five to ſeven or eight greeniſh-white flowers. Bractes trifid or undivided. Segments of the calyx ovate, pointed, hairy, viſcid. Petals roundiſh, a little pointed, with three nerves united at their baſe, yellow white with a greeniſh tinge. Germ half-inferior. Styles club-ſhaped[x].

Dr. Withering, who has deſcribed it under the name of *petræa*, in the additions to his Arrangement of Britiſh plants, remarks that the ſtem is about two inches high, that the root-leaves are moſtly three-cleft, that the petals are thrice as long as the calyx, each marked with three pale green lines, that the whole plant is hairy, the hairs being long, tranſparent, tapering to a fine point, jointed like a Conferva, and ſecreting a glutinous liquid. In other reſpects his own deſcription agrees with Dr. Smith's; but what he has ſet down from Linneus, belongs to the true *petræa*. None of his ſynonyms ſeem to appertain to this ſpecies.—Dr. Smith ſays that we cannot refer our *palmata* to any ſpecies of Haller, Allioni, Scopoli or Villars, though it comes in ſome points near the *exarata* of the laſt.

Native of Denmark and Wales. We are indebted to the indefatigable reſearches of J. Wynne Griffith, Eſq. for this beautiful addition to our Flora. He found it on the rocks of Cwm Idwell, above Llyn Idwell, near Twll dû, in North Wales, at the end of may. It flowers from april to june[y].

43. This approaches a little in the form of the leaves to *cæſpitoſa*, but it bears a flower like that of *Hirculus*[z]. It is ſufficiently diſtinguiſhed by the three cuſps or prickly points at the end of the leaves.

Native of Groenland, where it was found by Rottboell[a].

44. Root-leaves greatly reſembling thoſe of *Antirrhinum Cymbalaria*, whence its trivial name, nine or ten lines wide, and ſeven or eight lines long, ſeven-lobed, ſhining, on petioles from an inch to two inches and a half in length. Stem a long ſpan in height, feeble, almoſt procumbent on the rocks. Stem-leaves few, having the lobes or notches more pointed. The leaves next the flowers are entire and ſeſſile. The ſtem and branches are villoſe towards the top. Petals half an inch long, three lines wide at the top, white veined with green at the baſe. Filaments two lines long: anthers greeniſh and minute. Calyx cut to the centre into narrow villoſe ſegments. Piſtil pale green. Capſule brown, three lines high. Seeds blackiſh.—Native of the Levant, on mount Ararat[b].

45. This is a ſmall annual plant, native of the Levant. It was introduced in 1788, by the late John Sibthorp, M. D. Regius Profeſſor of Botany at Oxford; and flowers in july[c].

46. This bears ſome ſimilitude to *S. Cymbalaria*, but differs from it in the ſhining ſmoothneſs of all the parts, in the colour, ſmallneſs and expanſion of the flowers, in the greater length of the ſtamens, and in having the flowering branches more elongated[d].—Native of the Levant.

Willdenow remarks, that it is different from *S. Cymbalaria*, though they are alike; but he doubts whether it be diſtinct from *S. hederacea*. I cannot help ſuſpecting that the ſpecies of Saxifrage have been too much multiplied.

47. Corolla white. Germ inferior. Native of Spain, in the mountains near Caſtell-fort[e].

48. Roots fibrous, long and ſlender, throwing out many procumbent leafy ſhoots, which grow matted together, forming thick tufts; from the common origin of theſe ariſes a ſolitary erect round ſtem, bearing two or three ſtraggling linear undivided leaves, and terminating in an upright panicle of a few large white flowers. Leaves alternate, linear, acute, pale green, ſmooth, their edges only often hairy with ſoft white woolly threads: the leaves on the ſhoots ſimple and undivided; thoſe at the bottom of the ſtem all deeply three-cleft, with the ſegments divaricate. Bractes ſolitary at each ſubdiviſion of the panicle, lanceolate, and clothed with ſhort viſcid hairs. Segments of the calyx lanceolate, acute. Petals elliptic-oblong, obtuſe, greeniſh-white, with three green lines, all united for ſome diſtance above their origin, and the central one moſtly branched near the top. Five of the ſtamens rather ſhorter than the other five. Styles ſtill ſhorter, nearly erect. Stigmas blunt. Germ half-inferior[f].

Dr. Withering remarks, that the ſtem, fruitſtalks and calyx are thickly ſet with ſhort hairs terminated by red globules, and that the reſt of the plant is thinly ſet with fine white hairs.

S. ajugifolia is very like this, but has all the leaves three-cleft or five-cleft; as well as more numerous, though much ſmaller and yellower flowers, with blunt petals not having the midrib branched at the top[g].

Native of Britain, Denmark, Switzerland, Auſtria, and France. Tufts of it often clothe rocks, where the inequalities are filled with black turfy earth, on the mountains of Wales, Scotland and the north of England, as on Snowdon, Ben Lomond, and Arthur's Seat near Edinburgh, Weſtmoreland, Yorkſhire, Malham, Settle, &c. Derbyſhire in Dovedale and Middleton-dale. Alſo on Chedder rocks in Somerſetſhire: flowering in may, and often again ſparingly in july and auguſt.

49. This has the appearance of the preceding, and is ſcarcely diſtinct from it. Stems in tufts, branched, proſtrate at the baſe; from the top of theſe ariſe flowering-branches, which are erect and ſimple. Stem leaves in cluſters, ſmooth or ſcarcely pubeſcent. In the axils are ovate or roundiſh villoſe bulbs. The leaves on the flowering-branches are few and entire. Flowers in corymbs; the primary one ſeſſile or ſubſeſſile, the lateral ones pedicelled. Calyx pubeſcent, with ovate blunt ſegments. Petals obovate, twice as long as the calyx. Stamens ſhorter than the corolla. Capſule ovate.—On the top of mount Atlas.

50. Stems in tufts, branched, ſlender, proſtrate. Leaves alternate, cluſtered, ſmall, ſpatulate or ſometimes linear, running down along the petiole. Pedicels filiform, ſhort. Segments of the calyx ovate, ciliate. Corolla white, twice as long as the calyx. Petals obovate.—On the ſummit of mount Atlas near Belide. They both flower very early in the ſpring[h].]

PROPAGATION AND CULTURE.

1. Pyramidal Saxifrage is eaſily propagated by offſets, which are put out from the ſide of the old plants

in plenty. Plant them in pots filled with freſh light earth, placing them in the ſhade during ſummer, but expoſed to the ſun in winter. Take off all the offsets, leaving the plants ſingle, which will cauſe them to produce a much ſtronger ſtem for flowering. Plant theſe offsets in ſeparate halfpenny pots, to ſucceed the old plants, which generally periſh after flowering. They will produce flowers the ſecond year.

2. 3. Are to be treated in the ſame way:—*mutata* (n. 3.) muſt be ſheltered from much wet and ſevere froſt.

4. May be increaſed by parting the roots: it loves a moiſt ſoil and a ſhady ſituation; and is never injured by cold.

[14. Increaſed readily by parting the roots, either in ſpring or autumn. It flowers early, and if cold winds prevail at that time, the plant ſhould be covered with a hand-glaſs; or, if in a pot, may be removed into the greenhouſe[i].]

15. This muſt have a ſhady ſituation and a loamy ſoil.

[18. This increaſes ſo faſt by runners, as to be even troubleſome. It is properly a greenhouſe plant; in mild winters indeed it will bear the open air, eſpecially if placed at the foot of a wall, or among rock-work; but in ſuch ſituations it is frequently killed in ſevere ſeaſons[k].]

20. 21. Like many of the other ſpecies, theſe may be propagated by offsets taken off in autumn, and planted in a ſhady ſituation.

24. [At the end of march divide a plant which has filled a pot the preceding year, into many ſmall pieces, taking care that each piece has a few fibres to it; plant about ſix of theſe in the middle of a ſmall pot, filled with a compoſition of loam and rotten leaves or bog earth, in equal parts, water them and ſet them by in a ſhady place for about a week, then plunge them in an open border, expoſed not more than half the day to the ſun; in dry weather water them once a day; the enſuing ſpring each pot will be covered with a profuſion of bloom: to continue this plant in perfection it muſt be thus treated yearly. It is very hardy, and diſdains all tender treatment.

26. Plant it in a pot of bog earth, and keep the pot in a pan of water, ſo that the earth ſhall be conſtantly moiſt: in winter ſet it under a frame, to guard againſt ſevere froſt. It will thrive very well in an open border, if moiſt and formed chiefly of bog earth, and throw out ſhoots which will take root. It may alſo be increaſed by cuttings of the ſhoots, which will ſtrike root under a cloſe glaſs towards the cloſe of ſummer. If the plant be kept in a pot, it muſt be renewed every two or three years[l].]

27. This ſpecies, growing upon bogs, is difficult to propagate in gardens, unleſs it be planted in looſe rotten earth, and kept conſtantly moiſt.

[This difficulty has been in great meaſure overcome by having a ſhady moiſt border filled with bog-earth. In ſuch a border many elegant plants of this and various other genera thrive tolerably well. Some of the Alpine Saxifrages require a pure air, and will not thrive within the reach of ſmoke.]

28. Part the roots early in autumn, that the plants may be well rooted before the dry weather in ſpring. It ſucceeds beſt in a moiſt ſhady ſituation, and a ſtiffiſh loamy ſoil.

29. The double White Saxifrage is increaſed by offſets, which the old roots put forth in great plenty. Tranſplant them in july, after the leaves are decayed, into freſh undunged earth, placing them in the ſhade until autumn, but in winter expoſing them to the ſun. Theſe plants will flower in april, and if they are in large tufts will make a handſome appearance. In the full ground they muſt have a ſhady ſituation.

48. This ſort propagates faſt enough by its trailing branches, provided it be planted in a moiſt ſoil and a ſhady ſituation, but it will not thrive on dry ground, or where it is much expoſed to the ſun. The beſt time to remove this or any of theſe plants is in autumn, that they may have the benefit of the winter's rain to eſtabliſh them well before the dry weather of the ſpring comes on.

[The above directions will ſuffice for the culture of all the other ſpecies of this numerous and elegant genus. They are moſtly perennial, and to be increaſed by offsets or parting the roots; many of them not growing very readily from ſeed. The few annual ſorts, which are to be increaſed by ſeed, are particularly ſpecified at the foot of the deſcriptions.

SAXIFRAGA. See *Æthuſa, Arenaria, Liguſticum, Pimpinella, Sagina, Saponaria, Satureia, Seſeli, Silene.*

Saxifraga aurea, Saxifrage, Golden. } See *Chryſoſplenium.*]

SCABIOSA. (*This is a modern name, which ſome derive from* ſcaber, *rough or rugged; but others with more reaſon from* ſcabies, *the itch, which diſorder the common ſort is ſaid to cure.*)

Nat. order of *Aggregatæ. Dipſaceæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Common Perianth* many-flowered, ſpreading, many-leaved: *leaflets* in various rows ſurrounding the receptacle and placed upon it, the inner ones gradually leſs.

Proper Perianth double, both ſuperior:—*outer* ſhorter, membranaceous, plaited, permanent; *inner* five-parted, with the *ſegments* ſubulate-capillaceous.

COR. *univerſal* equal, often from unequal ones.

Proper one-petalled, tubular, four or five-cleft, equal or unequal.

STAM. *Filaments* four, ſubulate-capillary, weak. *Anthers* oblong, incumbent.

PIST. *Germ* inferior, involved in its proper ſheath as in a calycle. *Style* filiform, length of the corolla. *Stigma* obtuſe, obliquely emarginate.

PER. none.

SEEDS ſolitary, ovate-oblong, involute, crowned variouſly with proper calyxes.

REC. common convex, chaffy or naked.

OBS. *Exterior corollets often larger, more unequal. Crowns of the ſeeds various in the different ſpecies.*

The primary diſtinction of the ſpecies is to be taken from the diviſion of the florets into four-cleft and five-cleft.

ESSENTIAL CHARACTER.

Cal. common many-leaved: proper double, ſuperior. *Recept.* chaffy or naked.

SPECIES.

DESCRIPTIONS, *&c.*

1. Root perennial, compoſed of many ſtrong fibres which run deep in the ground. Stems ſeveral, ſtrong, channelled, upwards of four feet high. Leaflets four or five pairs, unequal in ſize and irregularly placed, ending in acute points. Flowers on naked peduncles at the ends of the branches, of a whitiſh yellow colour, and appearing at the end of june.

[Calyx ſhorter than the flower. Fruit half-ovate. Receptacle globular, with lanceolate channelled permanent chaffs. Seeds quadrangular, crowned with eight teeth, four larger and four ſmaller alternately. Pappus having twenty patulous rays [m].

Involucre oblong, four-cornered, membranaceous-chaffy, ſtriated, ſubvilloſe, ending in eight ſetaceous ruggediſh unequal teeth. Seed ovate, ſtriated, pale, narrowed into a ſhort ſtipe. Pappus ſilky-aſh-coloured, very ſhort, one-leafed at the baſe, divided at top into ſeveral villoſe or plumoſe rays. Albumen fleſhy. Embryo greeniſh yellow [n].

Villars ſays it is the largeſt of all their ſpecies, growing to the height of five or ſix feet, and that it is frequently miſtaken for the Great Centaury, from the ſimilitude of its leaves to thoſe of that plant.

According to Haller it is three or four feet high, with a hollow branched ſtem reſembling that of Sambucus Ebulus; the root-leaves are elliptic, the reſt pinnate with ſix or ſeven pairs of leaflets, the outmoſt of which is very large. He makes it a *Dipſacus* from the form of the ſeed-crown.

Native of the Alps of Switzerland, Dauphiné and Italy. Ray found it abundantly on Thuiri, one of the higheſt parts of the Jura chain. Haller ſays it is common about Aigle.

Ray calls it *Great Mountain Scabious*. Gerarde, who names it ſimply *Mountain Scabious*, ſays that the root grew in his garden to the bigneſs of a man's body. It was cultivated here in 1570, by Mr. Hugh Morgan, as appears from Lobel [o].

2. Native of the Cape of Good Hope, where it was found by Thunberg.

3. Stem ſuffruticoſe, rugged. Leaves ovate, ſerrate, with two teeth at the baſe. Peduncles terminating, very long [p].

In the *amoenitates* it is ſaid to reſemble *leucantha* very much; the ſtem to be ſhrubby and naked; the leaves naked, the lower ones obovate ending in the petiole, the reſt lanceolate, ſeſſile; two linear ſtipules from the axils; ſcales from the calyx roundiſh; corollets tomentoſe on the outſide, with the outmoſt ſegment a little larger than the others.

Native of the Cape of Good Hope. Cultivated by Mr. Miller in 1731 [q]. Omitted, with ſeveral other ſpecies, in the later editions of the Dictionary. It has been long known in the Dutch gardens.

4. This is a ſmooth plant, with grooved filiform branches, the younger ones ſubpubeſcent. Leaves quite entire, long, narrow, bluntiſh, ſometimes pinnatifid at the baſe, the ſegments ſolitary, linear, ſhorter by half than the leaf. Peduncle filiform, terminating the branches, one-flowered. Calyx-ſcales very blunt, ſubpubeſcent. Common corolla few-flowered. Corollets white, pubeſcent on the outſide [r].

Native of the Cape of Good Hope, where it was found by Thunberg and Maſſon. Introduced by the latter in 1774. It flowers from july to ſeptember [s].

5. This is an herbaceous plant, of the ſtature and with the ſtem and flowers of *Sc. rigida*. Stems round, ſimple, rugged. Leaves ſeſſile; leaflets linear, acute, with leafy rudiments of branches from the axils. Flowers terminating, on long peduncles ſolitary. Florets between the ſcales of the calyx, white [t]. They are ſaid in the deſcription to be unequal, but in the ſpecific character to be equal.—Native of the Cape of Good Hope.]

6. This is an annual plant, with ſtems riſing four or five feet high, and dividing into ſeveral branches. Leaves hairy, cut almoſt to the midrib. Flowers ſmall, of a pale purpliſh colour.

[Calyx and chaffs mucronate-awned, as in *Sc. ſyriaca* [u].

Native of Tranſylvania; and cultivated in the Ox-

[m] Linn. ſpec. [n] Gærtner. [o] Hort. kew. [p] Linn. mant. [q] Hort. kew. [r] Willdenow. [s] Hort. kew. [t] Linn. ſuppl. [u] Linn. ſpec.

ford

Digitized by Google

ford botanic garden by Jacob Bobart in 1699[x]: from ſeeds which were ſent by the celebrated Hermann[y].

7. Root annual. Stem hairy. Leaves ſerrate. Flowers ſubſeſſile in the forks of the ſtem. Calyx ſcarcely any, but the chaffs collected into an ovate cone, imbricate, awned, and ovate themſelves. Pappus hemiſpherical, with twenty toothlets[z].

Native of Syria. Cultivated in 1699, by Jacob Bobart[a], from ſeeds ſent to him from Aleppo. This, and the preceding are very lofty for annual plants, attaining the height of a man, and that even more[b].]

8. Root perennial. Lower leaves almoſt entire, ſerrate. Stem ſtiff, two feet high, bifid at top, ſpreading; in the diviſion ariſes a naked peduncle, which, as alſo the diviſions, are each terminated by a ſingle flower, compoſed of many white florets.

[Leaves linear, pinnate: leaflets decurrent; the loweſt rugged. Flowers ſubglobular, white. Calyx hemiſpherical, imbricate. The lower ſegments of the corollets bent down and a little longer than the reſt[c].

Involucre four-cornered, oblong, membranous-coriaceous, ſtriated, terminated by four acuminate larger toothlets, and as many ſhorter blunt ones. Seed ſhorter than its involucre, ovate-oblong, rhomb-compreſſed, attenuated into a very ſhort pappigerous ſtipe. Pappus very ſhort, with about ten converging rays, feathered or villoſe. Albumen thin. Embryo inverted[d].

Native of the South of France and Piedmont.—Cultivated in 1739, by Mr. Miller[e]; who has it under the name of *rigida*.

9. Root perennial, oblong, blackiſh, near the thickneſs of the little finger, often growing obliquely, ſtumped at the lower end ſo as to appear as if bitten off, whence its trivial name, and furniſhed with long whitiſh fibres. Stem from a foot to eighteen inches in height, upright, branched at top, round, rough with hair, and often of a reddiſh colour: the branches are lengthened out, and each bears one flower. Root-leaves ovate, quite entire, blunter than the others; ſtem-leaves lanceolate, the lower ones remotely toothed, but the upper ones entire; all dark-green, rather coriaceous, harſh and hairy. Flowers in nearly globular heads. Calyx hairy. Corolla violet or dark purpliſh blue, varying to fleſh-coloured and milk-white, nearly regular, but the uppermoſt ſegment ſomewhat longer than the other three. Outer perianth four-cornered, with four ſhallow clefts fringed with white hairs: the inner, which Withering calls the nectary, incloſing the germ, crowned with a concave glandular receptacle, armed with four or five ſtrong reddiſh-black briſtles. Beſides this apparatus, each floret is furniſhed with a green ſpear-ſhaped floral leaf, terminated by a white taper briſtle. Filaments almoſt twice the length of the corolla: anthers violet, with white pollen. Germ very ſmall, whitiſh; ſtyle, whilſt the anthers are ſhedding their pollen, the ſame length with the lower lip of the corolla; ſtigma round, flat, with a depreſſion in the middle. Seed oblong, angular, grooved, beſet with rough hairs and crowned with five briſtles[f].

Native of Europe, in paſtures; flowering from auguſt to the end of october. It varies much; according to Haller, the flowers are ſometimes proliferous, and the leaves are ſometimes gaſhed: the flowers not only vary in colour but are alſo double: with us the plant is commonly hirſute, but it is more often deſcribed as ſmooth by foreign authors.

Mr. Curtis remarks, that in the garden it grows more branched.

In days of ſuperſtition it was fabled, that the Devil, envying the good this herb might do to mankind, bit away a part of the root. This appearance of a ſtumped root is not peculiar to Succiſa, but is found in Plantain and many other herbs, when full grown.

According to Bergius, the root is aſtringent, and the infuſion of it bitteriſh, but not unpleaſant[g]. A ſtrong decoction of it, continued a good while together, is an empirical ſecret for gonorhoeas. Linneus ſays, that the dried leaves are uſed to die wool yellow or green[h].

10. Root annual. Stem not hiſpid. Branches patulous. Root-leaves like thoſe of the Daiſy, ovate, bluntiſh, rugged, more acutely ſerrate; ſtem-leaves few; branch-leaves lanceolate, embracing, ciliate at the baſe, ſeldom toothed or pinnatifid, very long. Calyx ten-leaved, ſhorter than the flower. Corolla purple: corollets two-lipped, the inner lip undivided, the outer three-parted, linear. Pappus with a toothletted crown[i].

Haller compares it with the *ſylvatica*, and doubts whether this be different from that.

Allioni at firſt had conſidered it as a new ſpecies: he remarks, that the leaves are ſometimes quite entire, but more frequently ſomewhat toothed; that the calyx is ciliate, with the ten leaflets alternately larger and ſmaller; that the florets are often eight, four-cleft and two-lipped; and the ſeeds ſilky crowned with toothlets.

Native of Germany, Switzerland, the South of France and the county of Nice. Cultivated in 1748, by Mr. Miller. It flowers from june to auguſt[k].

11. Stem a foot high, rugged, brachiate. Root-leaves oblong, ſomewhat rugged: ſtem-leaves widiſh at the baſe. Panicle dichotomous. Peduncles very long. Corolla blue. Calyx the length of the corolla.—It differs from the preceding in the root-leaves not being undivided, the ſtem-leaves being wider at the baſe, and in the calyx not being ſhorter by half than the corolla. It is not known from what country it comes[l].

12. Native of the Cape of Good Hope, where it was found by Thunberg.

13. This alſo is a native of the Cape, and was found there by Thunberg.]

14. This riſes with a ſtrong branching ſtalk four or five feet high, cloſely armed with ſtiff prickly hairs; lower hairs ſpear-ſhaped, about ſeven inches long, and near four broad in the middle, deeply cut on the ſides; ſtem-leaves more entire, ſome of them ſharply ſerrate; thoſe at the top linear and entire. Flowers from the ſides and at the top of the ſtalks, white and each ſitting in a briſtly calyx. Root biennial.

[Chaffs linear, longer than the ſeeds, deciduous. The plant is twelve feet high; and, according to Gmelin, the flowers are yellow[m].

Native of Tartary; and perhaps of Italy.

According to the Kew catalogue, it was introduced in 1779, by Chevalier Thunberg; but if it be the *altiſſima* of Miller, he cultivated it before 1759.

15. Root perennial, long, ſpindle-ſhaped, moſtly branched, running deep into the ground. Stem from one or two feet to near a yard in height, branched, rough with briſtles which rather point downward, towards the bottom ſpotted with dark purple. Leaves for the moſt part hairy; radical ones numerous, lanceolate, more or leſs ſerrate; ſtem-leaves pinnatifid, often gaſhed; the upper ones are entire: the ſtem-leaves are embracing. Branches ſpreading, each terminated by a ſingle flower, compoſed of very numerous pale-purple florets, of which the outmoſt are larger, labiate, and give the whole a radiate figure; they are a little villoſe within. The outer perianth is four-cornered and hairy, with four ſmall teeth; the inner incloſes the germ, and is crowned with a concave receptacle, ſet with ſhining glands on the inſide, and armed with eight or twelve ſpear-ſhaped ſerrate greeniſh briſtly ſubſtances, hairy at the baſe. Filaments of the ſame length with the corolla, with fleſh-coloured or pale purple anthers, which in the outer florets are abortive. Germ four-cornered, covered with numerous ſtiffiſh hairs, and crowned with a bell-ſhaped pappus formed of numerous aſh-coloured briſtles. Style longer than the corolla. Receptacle bearded with hairs ſhorter than the germs. Seed quadrangular, crowned by the perianth, which forms a briſtly villoſe pappus[n].—Linneus, in his Species plantarum,

remarks,

Digitized by Google

remarks, that the fruit is very like that of *S. tatarica*, but without chaffs.

Native of Europe, both in paſtures and corn fields, but more commonly in the latter: flowering in july and auguſt. The flowers and whole plant are much larger than *S. Succiſa*; the leaves are more jagged; it flowers earlier, and affects a drier ſituation [o].

The flowers, held over the ſmoke of tobacco, in a few minutes become of a moſt beautiful green [p]. The plant is ſlightly aſtringent, bitter and ſaponaceous. This ſpecies, as well as the *Succiſa* has been recommended internally in coughs, aſthmas, malignant fevers, lues venerea, epilepſy, &c. and externally in the ſcurvy, itch, tetters, &c.: but woe be to him who truſts on ſuch broken reeds.

In corn-fields it is undoubtedly a troubleſome weed, but in graſs, being a hardy plant, and producing a large quantity of foliage, which is not refuſed by kine, horſes or ſheep, it may perhaps be conſidered rather as uſeful [q].

It varies much in the diviſions of the leaves, and ſometimes they are all entire. The whole plant is ſometimes ſmooth. It occurs with white flowers:—with the calyx widened and longer than the flower:—and with the corollas five-cleft and equal, with a four-leaved involucre [r].

In Yorkſhire, the common Field Scabious is known by the name of *Great Blue-caps*.

16. Stem villoſe, upright. Leaves ſubvilloſe: the lower obovate, crenate or crenate-gaſhed, with wide, unequal, blunt notches; the upper pinnatifid at the baſe, with the outer lobe larger. Heads of flowers ſmall, cloſe, oblong when the fruit is ripe, one in each forking; the lower ſeſſile, the upper peduncled. Calyx many-parted, compoſed of linear leaflets, ſhorter than the head, bent down after the flowering is over. Corollets ſmall, ſubvilloſe. Outer perianth membranaceous ſmall; inner very ſmall, radiate. Seed grooved, ſubvilloſe. Receptacle ſlender, elongated, briſtly.—Native of Algiers [s]: alſo of Sicily.

17. This is an annual plant, native of Siberia.

18. Root perennial. Stem herbaceous, green, round, hollow, hiſpid with ſtiffiſh hairs ſpringing from black (or deep purple) dots, ſubdichotomous, erect, from one foot to two feet high. Leaves veined, acute, hirſute on both ſides; the lower ovate, tooth-ſerrate, never laciniate or gaſhed, three, four or five inches long; the upper linear-lanceolate and quite entire: thoſe by the ground and the next above them often attenuated into a very long winged petiole; the reſt ſeſſile. Peduncles very long ſupporting purple flowers, longer than the leaflets of the common calyx, which are lanceolate and ciliate below. The difference between the outer and inner corollets is not very great; the former however have the ſegments ſo much longer as to give the flower a title to be called radiant. Between the florets are villoſe and very ſhort briſtles inſtead of ſcales, as in *Sc. arvenſis*. Fruit convex, ſcarcely to be diſtinguiſhed from that. Seeds pale brown, ſomewhat hairy, crowned with the outer perianth, which is only a very ſhort irregular rim, and alſo with the inner, which is bell-ſhaped, commonly ten-toothed, with the teeth ending in an awl-ſhaped briſtle, but caducous [t].

Villars remarks, that this plant varies much; that the leaves are either entire at bottom, but towards the middle of the ſtem cut with large teeth, or elſe toothed at bottom and laciniate or pinnatifid at the baſe in the upper part of the plant; that the ſtems are two feet high, and in ſome places even three or four; that the corollets are more or leſs irregular, the outer ones having the lower ſegments long enough to place this plant among the radiant Scabiouſes, though improperly, and that the colour of them is more or leſs red.

Native of Germany, Switzerland, Auſtria, Carniola, and Piedmont, in woods, among buſhes, and ſometimes in fields; flowering the greater part of the ſummer.—It was cultivated in 1748, by Mr. Miller [u].

[o] Curtis. [p] Engl. bot. [q] Curtis. [r] Haller and Willdenow. [s] Desfontaines. [t] Jacqu. obſ. [u] Hort. kew.

19. Root-leaves villoſe, aſh-coloured, deeply pinnatifid; with the pinnules blunt, diſtinct, the lower ones linear and entire, the upper gradually wider, blunt, gaſh-toothed. Stem-leaves bipinnate, with the leaflets linear, narrow, unequal, ſcarcely pubeſcent. Common calyx ſhorter than the corollas, many-parted; the leaflets linear, acute. Seeds gathered into a ſmall round head, deeply grooved. Outer perianth ſhort, membranaceous; inner five-briſtled, brown. Receptacle chaffy. Allied to *S. Columbaria*, and perhaps only a variety of it. The ſtem is ſhorter, the lower leaves villoſe and aſh-coloured, and the head of flowers only half the ſize [x].

According to Villars, the ſtems are a foot and half in height; the lower leaves villoſe and pinnate: the ſtem-leaves leſs villoſe, narrower, and bipinnate; the peduncles very long; calyx-leaves linear, unequal, the length of the flowers; theſe are hemiſpherical, deep blue; ſeeds villoſe, marked with eight ſtreaks, crowned with a little open rayed membrane, of the ſame length with the five ſtarry rays which almoſt adhere to the centre. It flowers very late, even in november, and is perennial.

Native of the South of France, the county of Nice, and Barbary. Cultivated in 1739, by Mr. Miller [y].

20. This is eaſily diſtinguiſhed from the other Britiſh ſpecies by its five-cleft corollas, much more radiant than they, that is, having the outer ſegments of the outer corollets much larger than the inner. It has the habit of *arvenſis*, but is lower and much more ſlender in all its parts. The ſtem-leaves are ſometimes bipinnatifid. The flowers are of a blueiſh lilac colour. The pappus or crown conſiſts of five brown briſtles as long as the corollet. Root perennial, tapering to a point [z].

Native of Europe, Barbary and Siberia, on hilly paſtures in a gravelly or calcareous ſoil; flowering from june to ſeptember.

Weigel unites this to *Sc. ochroleuca*, under the name of *Scabioſa polymorpha* [a].

21. All the leaves are tomentoſe, the bottom ones ovate, crenate, like thoſe of the Daiſy; the next ſemipinnate with the pinnas ſhort and bluntly lanceolate, ſemipinnate alſo, or toothed, with the extreme pinna larger. Stem, except one pair of pinnate leaves, naked, half a foot or a long ſpan in height. Flower ſingle, radiate, purple, with the ſcales of the calyx ovate-lanceolate, not longer than the flower [b].

Allioni does not altogether inſiſt that this is a different ſpecies from the *columbaria*. He has given a figure of it, as it commonly appears; and alſo of a variety, with the leaves more deeply pinnatifid, having the extreme pinna roundiſh of a ſilky ſubſtance, the ſtem naked and one-flowered.

Scopoli deſcribes it under the name of *grandiflora*. Desfontaines has adopted his name, and remarks, that it is allied to *columbaria*, but differs in having the ſtem-leaves ſimply pinnate or pinnatifid, with the terminating lobe lanceolate: the corollas are a third part larger.

Native of the Pyrenees, Switzerland, Savoy, Lombardy, Barbary. Allioni marks both this and *columbaria* as biennial.

22. Root annual. Stem herbaceous, a foot high, dichotomous, divaricating, red, weak. Leaves petioled, almoſt naked, a little hairy: the lower ones lyrate; the upper ſubpinnate, linear. Peduncles from the forkings, long, ſcarcely pubeſcent, purple. Calyx eight-leaved: leaflets lanceolate, reflexed, much longer than the corolla. Corolla equal (by no means radiate) red. Corollets ſmall, irregular but equal in ſize, much narrower than the calycle. Stamens whitiſh, longer than the corollets. Pappus a bell-ſhaped crown, plaited, many-toothed, with eight calluſes in the centre. Star ſtiped, conſiſting of five dark-purple briſtles, longer than the floret. It differs principally from *Sc. maritima* in the flowers not being radiate.—Native of Sicily [c]. Introduced in 1782, by Abbé Pourret [d].

[x] Desfontaines. [y] Hort. kew. [z] Smith, brit. and Withering. [a] Willdenow. [b] Haller. [c] Linn. mant. [d] Hort. kew.

Digitized by Google

S C A

23. Root perennial, woody, divided at top. Stems ſeveral, erect, a foot high, ſtiff, ſcarcely ſtriated, ſmooth except at bottom where they are villoſe, ſimple, covered at the baſe with imbricate ovate acuminate ciliate embracing ſcales, being the permanent baſe of the leaves. Leaves thickiſh, connate at the baſe, ſubciliate, an inch long: on each ſide are five pinnas, narrow-linear, longer outwards, the end one four times as large as the reſt: ſtem-leaves few, the uppermoſt linear, undivided, far remote. Peduncles oppoſite above, ſomewhat branched, elongated, one-flowered. Common perianth turbinate, ſomewhat hairy, one-leafed, five-cleft, with the ſegments awl-ſhaped: proper perianth four-toothed. Corollets nearly equal, ſcarcely longer than the calyx, few, villoſe. Chaffs lanceolate, only half the length of the corollets [e].

Vahl gathered it at Cape Zebibo, in the kingdom of Tunis, flowering in the middle of july. He ſays it is Boccone's plant as it appears in Vaillant's herbarium.

Desfontaines deſcribes a plant under the name of *S. urceolata*, which he found on the ſea ſhore of Barbary, which he ſays is certainly Boccone's; but that Vaillant's herbarium has a different ſpecies under the ſame name. He refers to the *divaricata* of Lamarck (illuſtr. n. 1311.) His deſcription differs from the above in ſome reſpects.—Branches numerous, oppoſite, divaricating, ſlender, dichotomous. Leaves ſmooth, ſhining: root-leaves lanceolate, toothed; the lower and middle ones deeply pinnatifid, with the pinnules linear, entire or toothed; upper branch-leaves linear-ſubulate, quite entire. Flowers ſmall, on long, leafleſs, ſtriated peduncles. Common calyx ſimple, goblet-ſhaped, ſhorter than the corolla, half ſix or eight-cleft, the ſegments narrow and acute, often alternately larger and ſmaller. Corollets radiant, funnel-ſhaped, pale-yellow, irregular in the ray, regular in the diſk. Proper perianth double: outer ſhort, with four blunt teeth; inner ſmall, five-briſtled. Seed oblong, four-cornered, ſmooth, grooved. Chaffs convex on one ſide, mucronate.

24. Calyx imbricate, hemiſpherical, with the ſcales ovate obtuſe [f].

Stem upright, branched, round, ſtriated, villoſe, a foot and half high. Branches in threes, long, like the ſtem. Lower leaves lyrate-pinnate, entirely villoſe: lower pinnas about three pairs, remote, linear, blunt, unequal; the lower of theſe ſmaller, more alternate, entire, the upper gradually larger, more oppoſite, toothed, decurrent: terminating pinna very large, very blunt, gaſhed, toothed. Stem-leaves embracing, linear, pinnate with ſolitary linear lobes, entire: the upper ones altogether lanceolate and quite entire. Peduncles elongated. Common involucre many-leaved, longer than the head of flowers: leaflets lanceolate, entire, villoſe [g].

Villars doubts whether his maritima be the ſame with that of Linneus's mantiſſa. Linneus, in his ſpecies, ſuppoſed it to be Boccone's plant, which is now referred to the preceding ſpecies, but he corrected that error in his mantiſſa.

Native of Italy, France and Japan.—It was cultivated in 1683, by Mr. James Sutherland, flowers here in july, and is an annual [h]. Thunberg found it flowering about Nagaſaki, in ſeptember and october.]

25. This is an annual plant. Stems three feet high, hairy. Leaves oblong, deeply notched; the upper ones cut almoſt to the midrib into fine ſegments. Flowers on long peduncles. Receptacles globular. Florets large, ſpreading open like a ſtar, of a pale purple colour.

[The lower leaves obovate-oblong, gaſh-ſerrate: the upper ones lyrate. Corollets of the diſk regular; thoſe of the ray have the three outer ſegments larger. Head of fruit globular. Seeds hairy, engraved at top with eight cavities. Pappus with the border of the ſtar wheel-ſhaped, membranaceous, rayed with forty briſtles: the central ſtarlet is five-rayed [i].

[e] Vahl. [f] Linn. mant. [g] Thunberg. [h] Hort. kew. [i] Linn. mant.

According to Gærtner, the involucre of the ſeed is turbinate, fungous, woolly, white, near the top very deeply eight-plaited, terminated by a wide rounded, membranaceous diſk, ſtriated in rays and toothletted at the edge. The reſt as in *atropurpurea*.

Native of Spain and Barbary; cultivated in 1596, by Gerarde. It flowers in july and auguſt [k].

Variety γ has the flowers ſcarcely radiate; the leaves linear and pinnate: the leaflets of the calyx have an elongated tooth on each ſide [l].

26. Stem herbaceous, dichotomous or proliferous. Leaves lanceolate, ſubpubeſcent, connate at the baſe; the lower ones ſubſerrate. Flowers axillary, ſubſeſſile. Calyx looſe, the length of the corolla. Corolla yellow, radiate, with the three outer ſegments larger [m].

Stem erect, villoſe, ſtriated. Outer perianth large, membranaceous, bell-ſhaped, ſtriated, toothletted; inner five-briſtled, villoſe at the baſe, pedicelled, ſcarcely longer. Seed deeply grooved, villoſe. Receptacle roundiſh. Chaffs ſetaceous, villoſe at the top [n].

It is an annual plant, native of Barbary and Egypt, in corn fields.—Cultivated by Mr. Miller in 1768 [o].

27. Calyx twelve-leaved, linear, recurved, the length of the corolla. Flower very dark purple, with white anthers. Fruit ovate. Receptacle ſubulate, with briſtle-ſhaped chaffs. Seeds four-cornered, terminated by an involute plaited præputium. Pappus compoſed of five briſtle-ſhaped rays [p].

Involucre of the ſeed from a globular baſe, which is eight-grooved, ending in a dome which is inverſely conical, membranaceous, terminated by an inflexed crenulate margin, and inſcribed on the ſides with eight raiſed opaque bows, incloſing oblong ſubdiaphanous areas. Seed ſubglobular, ſmall, ending in a filiform ſtipe, terminated by a briſtle-ſhaped, five-rayed pappus. Albumen thin. Embryo inverted, white [q].]

It is an annual (biennial) plant, and the flowers are very ſweet. There is a great variety in their colour, ſome being of a purple approaching to black, others of a pale purple, ſome red and others variegated. It alſo varies in the leaves, ſome being finer cut than others: and ſometimes from the ſide of the calyx come out many ſlender peduncles ſuſtaining ſmall flowers; like the (proliferous or) hen-and-chicken Daiſy.

[We have no certain account of what country the Sweet Scabious is a native. Cluſius relates, that he received the ſeeds of it from Italy, under the name of Indian Scabious, that the ſeeds which he gave to ſome friends produced paler-coloured flowers, and that ſeeds were ſent him from Vienna which came from Spain, and alſo produced flowers of a paler red. Parkinſon ſays, that this reputed Indian Scabious is verily thought to grow naturally in Spain and Italy. Cluſius does not affirm that, nor does Parkinſon give any authority. Linneus mentions it as a native of India with a note of doubt. Miller gives it expreſsly as a native of that country. But in the Kew catalogue its place of growth is left unſettled [r]. In all probability it is not a native of India, but of the South of Europe. If however the S. cochinchinenſis of Loureiro ſhould turn out to be the ſame with this, it would determine the matter.

It flowers from june to october. Parkinſon, in 1629, ſays, "If it be careſully defended from the extremity of winter, it will flower the ſooner the next year, as I myſelf have often found by experience." It flowered firſt with Cluſius in 1591.

It is remarkable that Parkinſon deſcribes it as having no ſcent; but perhaps he meant to ſpeak only of that which has paler flowers, and has certainly not ſo much of the muſky ſmell. Cluſius however, makes no mention of the ſweetneſs of theſe flowers.]

28. This is a low perennial plant, with a branching ſtalk ſpreading wide on every ſide; the leaves are of a ſilvery colour; the flowers are ſmall, pale, and have no ſcent.

[The ſtem has white hairs thinly ſcattered over it.

[k] Hort. kew. [l] Linn. mant. [m] Idem. [n] Desfontaines. [o] Hort. kew. [p] Linn. ſpec. & ſyſt. [q] Gærtner. [r] Cluſ. hiſt. 2. p. 2. Park. parad. Curt. magaz.

Root-

Digitized by Google

Root-leaves ſomewhat toothed; ſtem-leaves undivided, ciliate towards the baſe. Calyx very hairy at the baſe, eight-leaved, recurved, length of the corolla. Corollas whitiſh with a blueiſh border. Corollets of the ray ſix, larger, with the upper lip very ſhort and bifid, the lower wide trifid blunt ſomewhat plaited equal. Corollets of the diſk white, regular, hirſute on the outſide. Stamens white [a].

Native of the Levant. Cultivated in 1713, by Mr. Thomas Fairchild. It flowers from june to october [b].

β. Leaves villoſe: root-leaves ſpatulate, narrow, blunt, toothed, running down into the petiole: ſtem-leaves deeply pinnatifid, with the ſegments linear-lanceolate, diſtinct, quite entire or ſometimes but more rarely toothed. Stem rough, villoſe, erect, dichotomous. Peduncles filiform, elongated, one-flowered. Common calyx hirſute, longer than the flowers, deeply many-parted: ſegments unequal, linear, erect, bent down when the fruit is ripe. Corollets ſilky, white or roſe-coloured. Seeds in a roundiſh head. Outer perianth ſcarioſe, wheel-bell-ſhaped, toothletted, ſtriated; inner five-briſtled, longer, the briſtles rufeſcent. Seed cylindrical, villoſe below, having eight or nine little holes in it.—It varies with a ſmooth ſtem and leaves. Native of Algiers [c].

29. Stem erect, ſtriated, ſubvilloſe, rough, ſimple or with a few upright branches. Leaves pubeſcent: thoſe next the root ovate or ovate-oblong, toothed, blunt, pinnatifid at the baſe, petioled; lower ſtem-leaves pinnatifid, with the terminating lobe ovate, blunt, toothed; middle ſtem-leaves bipinnate, with the ſegments unequal, linear, acute; upper ones pinnate, with the pinnules linear-ſubulate. Peduncles long, ſtriated. Common calyx ſhorter than the corollas, hirſute, with the leaflets pinnatifid. Flowers the ſame ſize with thoſe of the Sc. columbaria. Corollets blue or violet, irregular in the ray, regular in the diſk. Outer perianth ſubcampanulate; inner five-awned. Germ oblong, ſlightly four-cornered. Receptacle convex. Chaffs membranaceous, awl-ſhaped, convex on one ſide. It is allied to S. columbaria, but differs in having a villoſe pinnatifid calyx.—Native of Algiers, on hills [d].

30. Leaves ſeſſile, a ſpan long, ſerrate or gnawn, the upper ones more ſharply, ſubtomentoſe but green, deeply toothed at the baſe with from one to three teeth on each ſide. Panicle dichotomous; the firſt diviſion pedunculiferous, the others floriferous at the top. Peduncles very long. Calyx ten-leaved, ſpreading, ſhort, almoſt equal, by no means imbricate. Corolla pale blue, longer than the calyx. Chaffs briſtle-ſhaped. Seeds oblong, eight grooved: crown membranaceous and with ſtars of five longer briſtles [e].

It is ſo nearly allied to S. africana, that it may be doubted whether it is not a variety [e].—Native of Africa.]

31. This has a weak ſhrubby ſtalk, which divides into ſeveral branches, and riſes about five feet high. Leaves ovate-lanceolate, three inches long, and an inch and half broad, deeply crenate, of a light green, and a little hairy. Peduncle terminating, ſuſtaining one pale fleſh-coloured flower.

[This ſpecies varies in the leaves: that variety with the leaves very finely cut, is diſtinguiſhed by Miller, under the name of *S. inciſa*. He thus deſcribes it.] The ſtalks are hairy, and divide into ſeveral branches. The bottom leaves are lanceolate crenate and entire; but thoſe on the upper part of the ſtalk are bipinnate. The flowers are produced upon long naked foot-ſtalks from the end of the branches; they are of a pale fleſh-colour and large, but have no ſcent.

[Native of Africa. Introduced in 1690, by Mr. Bentick. It flowers from july to october [a].

32. Plant a foot and half high, hirſute all over, biennial, flowering from may to july. Stem round, weak, purpliſh at bottom. All the leaves pinnate, petioled and oppoſite: pinnas diſtant, oblong, acute, ſome quite entire; others here and there gaſhed at the top. Peduncles terminating. Leaflets of the common calyx hirſute, acute, entire. Corollets purple, ſomewhat hairy on the outſide, funnel-ſhaped, with the ſegments almoſt equal and blunt. Filaments ſcarcely exceeding the corolla. Anthers purple. Seeds hirſute, crowned by the outer perianth which is membranaceous wide ſhaped like a baſin and ſtriated, alſo by the inner perianth which is pedicelled and ends in five awl-ſhaped and very ſpreading briſtles [b].—Native of France about Montpellier.

33. The whole plant is extremely hirſute. It has ſcarcely any ſtem.—Native of the Cape of Good Hope [c].]

34. This riſes with a ſhrubby ſtalk three feet high, and divides into ſeveral woody knotty branches. Leaves narrow, ſilvery, entire, four inches long and a quarter of an inch broad. The flowers ſtand upon very long naked peduncles at the end of the branches, and are of a fine blue colour.

[Linnæus remarks, that the leaves are ſo cloſely cluſtered on the ſtem as to be almoſt imbricate, and that the calyxes are obtuſe. Willdenow informs us, that in the wild plant the leaves are ciliate at the edge with white hairs.

Native of Candia and Sicily. Mr. Miller diſtinguiſhes them, and ſays that the plant from Candia has] ſhorter and much broader leaves, not ſo white as thoſe of the Sicilian; that the flowers are not ſo large, and are of a pale purple colour.

[Gerarde cultivated it in 1596 [d].

35. Root divided above. Stems fruteſcent at the baſe, erect, ſimple: flowering-ſcape among the leaves, grooved-angular, almoſt leafleſs, a foot high. Leaves at bottom almoſt like thoſe of Statice Limonium but ſmaller, aggregate, ſcarcely an inch in length, oblong, ending in the petiole, thick, above ſmooth and veinleſs, beneath veiny-wrinkled, with the margin reflexed, emarginate: on the flowering-ſcapes at bottom two under the loweſt peduncles, lanceolate, acute, with a ſingle tooth at the baſe on each ſide, the upper ones linear. Peduncles two at bottom from the axils of the leaves of the ſcape; three above, very remote, terminating; the lateral ones branched a little. Leaflets of the common calyx lanceolate, bluntiſh, tomentoſe, hoary. Outer perianth ſhort, unequally toothletted; inner twice as long with five purple briſtles. Corollets equal, tomentoſe on the outſide. Chaffs linear, narrower at the baſe, length of the florets, tomentoſe.—Native of Sicily [e].]

36. This has a perennial root, from which ariſe three or four ſtalks, the lower parts of which have linear leaves about four inches long, and the eighth of an inch broad, of a ſilvery colour, ending in acute points. The upper part of the ſtalk is naked for ſix or ſeven inches in length, and ſuſtains at the top one pale-blue flower.

[Stems branching at the baſe, procumbent, knobbed. Leaves cluſtered, oppoſite, reſembling thoſe of graſs, quite entire, drawn to a point at each end, connate or ſheathing at the baſe, ſilvery, ſhining, with villoſe hairs preſſed cloſe to the leaf. Peduncle terminating, long, leafleſs, pubeſcent, round not ſtriated, one-flowered. Common calyx villoſe, with linear ſegments, nearly equal, almoſt as ſhort again as the flower. Head of flowers flat. Corollets blue, longer and irregular in the ray; the ſegments toothletted. Outer perianth membranaceous, bell-ſhaped, ſtriated; inner five-briſtled, ſcarcely longer. Seed villoſe, cylindrical. Receptacle oblong, with concave, mucronate chaffs [f].

Native of the mountains of Dauphiné, Carniola, Italy, Switzerland, Sileſia, Barbary. Cultivated in 1683, by Mr. James Sutherland. It flowers in july [g].

37. Stem herbaceous, erect, a foot high, ſimple, ſtriated, ſomewhat hairy. Leaves an inch and half long, ſmooth above, hairy on the veins underneath; the lower ones oblong, undivided, groſsly and bluntly ſerrate, ending in a petiole ſhorter by half than the leaf: the upper ones ſeſſile, pinnatifid; ſegments lanceolate, wider outwards, gaſh-toothed, the end one

[a] Linn. ſyſt. [b] Hort. kew. [c] Desfontaines. [d] Idem. [e] Linn. mant. [f] Linn. ſyſt. [g] Hort. kew.

Digitized by Google

very large, and oblong. Peduncles terminating, ſolitary, elongated, leafleſs, hairy, one-flowered. Common calyx eight-leaved; leaflets lanceolate, tomentoſe at the baſe, length of the corolla. Outer perianth grooved, angular, ſhort, having twelve or fourteen teeth, erect, with a purple mouth: inner having five briſtle-ſhaped ſegments, a little ſhorter than the corollets and purple. Corollets hairy on the outſide. Chaffs lanceolate, the length of the calyx.—*S. palæſtina* differs from this in having the ſegments of the corollets in the ray trifid; the calycle of the ſeeds is ſpread out flat, as in *S. ſtellata* [h].—Native of the ſhore of the Dardanelles.

38. Stem a foot high, round. Leaves broad-lanceolate, cut with a few gaſhes, and pubeſcent: the uppermoſt linear-lanceolate, pinnatifid at the lower baſe. Peduncles very long. Flowers white, or lemon-coloured, the length of the calyx. Corollets in the ray very beautiful, all its ſegments, as well the two upper ſmall ones, as the three outer ones, ſubdivided into three ſegments. The fruit is the ſame as in *Sc. ſtellata.*

Native of Paleſtine, where it was found by Haſſelquiſt [i]. Introduced in 1771, by Monſ. Richard [k].

39. Stems a foot high, aſcending, ſubtomentoſe. The leaves have ſtiffiſh hairs ſcattered over them: the upper ones ſimply pinnate. Branches very few, often none. Flower white, not ſhorter than the calyx; which is many-leaved and ſpreading. Seeds as in *Sc. ſtellata.*—Native of Siberia, on rocks [l].

40. The ſtem-leaves are not always ciliate at the baſe, Linneus's ſpecific character therefore is not accurate in that reſpect.

Native of the Ukraine [m]. Allioni ſays it is found alſo in Piedmont.

41. Root perennial, whitiſh brown, the thickneſs of a finger and woody. Stem round, equal, either wholly ſhining, or wholly or only at bottom pubeſcent, pale green, but moſt frequently tinged with purple at the baſe and at the axils of the leaves, frequently the colour is very dark; it is from a foot to three feet in height, and erect. The primary diviſion is dichotomous; the other diviſions are by elongated peduncles. Root-leaves in plants of the firſt year, and lower ſtem-leaves obverſely lanceolate, entire, unequally ſerrate, ſometimes pinnatifid, attenuated into a very long petiole, ſubtomentoſe or ſmoothiſh on both ſides. As the plants advance the leaves are more cut, and become pinnatifid or ſubbipinnatifid, and more ſmooth. Stem-leaves ſmooth, the upper ones quite ſimple, the next pinnate, the lower bipinnatifid; the pinnules are linear acute and confluent. Petioles connate at the baſe. In larger plants the leaves are much more divided; and ſometimes they are all pinnatifid gaſhed, except the uppermoſt. The inner perianth has five briſtles. The corollets are conſtantly of a pale ſulphur-colour. Fruit ovate. Seed, or rather its involucre, ovate, eight-grooved, villoſe at the baſe, crowned with a membranaceous margin [n].

Linneus remarks, that it is allied to *Sc. columbaria.* It is a biennial plant, native of Germany; and was cultivated in 1739, by Mr. Miller. It flowers in july and auguſt [o].

42. Root annual. Stem filiform, brachiate, with a ſubdichotomous panicle. Peduncles axillary, filiform, long. Calyx-leaflets ovate, very acuminate. Seeds crowned with a feathered down, and a thicker longer awn cloſe to it. Peduncles and calyxes tomentoſe [p]. Proper involucre of the flower cylindric-pitcher-ſhaped, fungous, eight-plaited, truncate at the top, and terminated by twelve or more very ſhort, briſtle-ſhaped toothlets. Receptacle ſlightly convex. Seed ovate-acuminate, attenuated into a ſhort pappigerous ſtipe. Pappus feathered, white, longer than the feed [q].

Native of the iſland of Crete or Candia:—of the South of Europe. Cultivated in 1739, by Mr. Miller. It flowers in july [r].

43. Suppoſed to be a native of Greece.]

[h] Vahl. [i] Linn. mant. [k] Hort. kew.

PROPAGATION AND CULTURE.

1. This may be propagated either by ſeeds or parting the roots. It loves a loamy ſoil.

6. Sow the ſeeds in a ſhady moiſt border; keep the ground clean, and allow the plants room to ſpread.

8. Part the roots in autumn, and ſet the plants in a light loamy ſoil.

14. Riſes from ſcattered ſeeds, and requires no care.

25. Sow the ſeeds in a bed of light loamy earth, where the plants are to remain; when they come up, thin them and keep them clean from weeds.

27. Sow the ſeeds of the Sweet or Muſk Scabious at the end of may or beginning of june, upon a ſhady border of freſh earth; for if they are too much expoſed to the ſun, and the ſeaſon ſhould prove dry, few of them will grow. And if they are ſown early in the ſpring, they will flower in the autumn, and the winter coming on, will prevent the ſeeds from ripening; beſides which, the flowers will be few and weak. Whereas if they are left to form a ſtrong root and leaves in the autumn, they will ſend up their flower-ſtems early in the next ſummer, branching out on every ſide, producing a great number of flowers, continuing in ſucceſſion from june to ſeptember, and producing good ſeeds in plenty.

When the plants ſown in may come up, tranſplant them into a bed or border of freſh earth, watering and ſhading them till they have taken root; and, having kept them clean from weeds, tranſplant them at michaelmas into the middle of the borders in the pleaſure-garden. It is very hardy, being rarely injured by cold, unleſs it ſhoots up to flower before winter: but it does not continue after ripening the ſeeds.

31. This, with the other African ſpecies, may be increaſed by cuttings, planted in a ſhady border, during any of the ſummer months. When theſe have put out good roots, plant them in pots filled with light loamy earth, and placed in the ſhade till they have taken new root; then remove them to a ſheltered ſituation till froſts come on, when they muſt be put into the dry ſtove or a glaſs-caſe for the winter, giving them as much free air as poſſible in mild weather. In the middle or end of april they may be removed into the open air in a warm ſituation.

34. This alſo may be increaſed by cuttings or by ſlips. When theſe have taken good root, plant ſome on a dry border near a ſouth wall, where they will live in common winters. But as ſevere froſt frequently deſtroys them, put ſome of the plants in pots, placing them under a frame in winter, giving them air in mild weather.

36. This, not producing ſeeds in England, may be increaſed by ſlips, planted on a ſhady border the beginning of april. When theſe have put out good roots, take them up with balls of earth, and tranſplant them where they are to remain. It loves a ſoft loamy ſoil, and a ſhady ſituation.

41. May be propagated by ſeeds, and will thrive any where.

[The above directions are ſufficient for the propagation and treatment of the other ſpecies, which are either hardy annuals, to be increaſed by ſeeds, or hardy perennials, to be increaſed by parting the roots.

COR. one-petalled, unequal. *Tube* long, with a longitudinal fiſſure. *Border* five-cleft, aſcending: *ſegments* directed

Digitized by Google

Flowers ſubradiate, white: florets about ſix fertile, the reſt male. Stamens longer than the florets, with purpliſh anthers. Outer ſeed hiſpid with jointed ſpines: inner rugged only, like both ſeeds of the central floret[t]. It is doubtful whether this be the ſame with *Sc. infeſta* of Forſkahl. According to Reichard it is not *Sc. infeſta* of Jacquin.—We do not know where it is a native.]

10. This is an annual plant with fine-cut leaves. The ſtalks riſe eight inches high, have at each joint a fine-cut leaf, and are terminated by an umbel of white flowers, with large heart-ſhaped petals. The horns (beaks) of this are longer than any of the other ſorts, and the peduncles are very hairy.

Native of the Levant, where it was found by Tournefort. [Cultivated by Mr. Miller in 1759.]

11. This is a low trailing plant, native of Virginia. [Cultivated by Mr. Miller in 1768.]

PROPAGATION AND CULTURE.

1, 2, 5, 6, 10, 11. Theſe will increaſe faſt by ſeeds, which, if permitted to ſcatter, will produce plenty of plants; theſe may be left in their place, or tranſplanted to any part of the garden, for they will grow in any ſoil or ſituation, and require no care.

4. Sow the ſeeds of Chervil in autumn, ſoon after they are ripe, either in drills or broad-caſt. Seeds ſown in the ſpring rarely come up, and if they do, the plants never thrive, for as ſoon as the warm weather ſets in, they ſoon wither and decay; whereas the plants which riſe in autumn, continue green all the winter, and in april they flower; ſoon after which the ſeeds ripen, and the whole plants decay. [This ſpecies will alſo maintain itſelf by ſcattered ſeeds.

DESCRIPTIONS, &c.

1. This is a ſmall tree or a ſhrub. Trunk upright, with a ſmooth aſh-coloured bark. Branches almoſt upright, unequal, rigid, ſmooth. Leaves on ſhort petioles, alternately ſmaller, ovate acute, almoſt entire or very ſlightly crenate, veined, rigid, with the end recurved a little, green, ſhining. Peduncles ſeveral crowded many times ſhorter than the leaves, one-flowered, deciduous, having ſmall calyx-form ſcalelets at their baſe. Flowers white[u].

Jacquin, who firſt diſcovered and named this ſpecies, ſays it is a ſhrub ten feet high; in thick coppices frequently throwing out very long branches like the vine. Leaves lanceolate-ovate or ovate-roundiſh, acute or obtuſe, quite entire, greaſy to the touch, deciduous, coming out afreſh after the flowers burſt forth, one, two or three from the ſame tubercle in alternate order. Flowers ſmall. Berries the ſize of a ſmall pea, yelloviſh red.

Native of the Weſt Indies. Diſcovered by Jacquin about Carthagena in New Spain, flowering in july, and ripening its fruit in ſeptember. Sloane found it in Jamaica. Swartz in the ſame iſland and in Hiſpaniola. The latter ſaw it flowering twice in the year, in january and june.

2. This is a ſmall tree, with the trunk a fathom high or more, upright and ſmooth; and the branches round, ſmooth, aſh-coloured. Leaves alternate, ovate-acuminate, membranaceous, ſtiffiſh, browniſh-green, beautifully veined and ſomewhat reticulate. Peduncles lateral, aggregate on the branches below the leaves, ſubſeſſile or on very ſhort pedicels, whitiſh green. Calyx, in the male, ſometimes but ſeldom five-leaved, white-ciliate, two ſmaller. Inſtead of the petals a ſmall yellow ſubvilloſe body in the middle of the calyx, which may be called a nectary. Filaments four or five, longer than the calyx, villoſe at the baſe. Anthers twin, yellow, villoſe. Calyx, in the female, four or five-parted, ciliate. A compreſſed fleſhy yellow rim at the baſe of the germ inſtead of petals. Berry the ſize of a large pepper-corn, pubeſcent, ſcarlet when ripe. It flowers in february; and was diſcovered in the iſland of Hiſpaniola by Swartz; who thinks it may perhaps be of a different genus from the preceding ſpecies[x].

[DESCRIPTION, *&c.*

Root perennial, creeping, jointed, covered at top with ſcales, which are the relics of departed leaves, among which it puts forth fibres. Stem upright, ſimple, a ſpan high, round. Root-leaves few: ſtem-leaves two, one involving the baſe of the ſtem with its ſheath, the other a little higher, each ſhorter than the ſtem. Villars remarks, that there are two or three joints on the ſtem, with a leaf at each, which is firm, rolled back, a little recurved, pointed and cylindrical. The floral leaves come out above the middle of the ſtem alternately, moſt frequently five in number, the lower ones longer, each proceeding from a ſheath, which is looſe and does not invert the upper part of the culm. Flowers from each axil of the floral leaves ſolitary, on upright peduncles, of a yellowiſh-green colour. Germs commonly three, but frequently four or five in a flower[y]. Pollich ſays, from three to ſix capſules to a flower; and one or two, ſometimes but ſeldom three ſeeds in a capſule.

Native of Lapland, Sweden, Denmark, Germany, Switzerland, Pruſſia, Dauphiné, Siberia, in marſhes.

DESCRIPTIONS, *&c.*

1. This riſes with a woody ſtem eight or ten feet high, dividing into many branches, covered with a brown rough bark. Leaves alternate on the branches, compoſed of ſeveral pairs of leaflets from ten to fifteen, each about an inch and half long, and a quarter of an inch broad at the baſe, leſſening gradually to the point, and having a few ſerratures on their edges; they are of a lucid green, and emit a turpentine odour when bruiſed. The flowers are produced in looſe bunches at the end of the branches; they are very ſmall, white, and have no odour.

[Linneus remarks, that the female flowers have ſtamens, but that they are barren.

Gærtner deſcribes the berry as ſpherical, the ſize of a pea, ſucculent, one-celled, one-ſeeded: cuticle papery, very ſmooth, ſhining, whitiſh: pulp fugacious: ſhell cartilaginous, hard, but it may be cut when ſoftened, ovate-turbinate, very obſcurely angular, ſomewhat wrinkled, divided into ſeveral cells, the central cell larger and having a ſeed in it, the outer ones (ſix at moſt) ſpurious, narrow, abounding in a fragrant aromatic oil. Seed one in each ſhell, of the ſame ſhape with the central cavity, or obovate, irregularly and deeply angular, acuminate downwards, pale.

The number of ſeeds is variouſly given by different authors. Adanſon and Gærtner ſaw only one ſhell. Feuillée mentions two ſeeds having the taſte of pepper, in the middle of a bright red berry filled with a gummy ſubſtance. All other authors aſcribe three ſeeds to Schinus[z].

Native of Peru.] Mr. Miller ſays, he has received the ſeeds both from Peru and Mexico. [The Maſtick tree was cultivated by Gerarde before 1597[a]. As alſo by Mr. Nicholas Lete, merchant of London, and Mr. James Garret, a moſt ſkilful apothecary, who received the ſeeds from Lord Hunſdon, Lord High Chamberlain of England; worthy (ſays Gerarde) of triple honour for his care in getting, as alſo for his curious keeping rare things brought from the fartheſt part of the world: which ſeeds we have ſown in our gardens, where they have brought forth plants of a foot high, and alſo their beautiful leaves: but notwithſtanding our care, diligence and induſtry, they have periſhed at the firſt approach of winter, as not being able by

[z] Gærtner. [a] Hort. kew.

reaſon

Digitized by Google

reaſon of their tenderneſs to indure the cold of our winter blaſts[b]. And yet we have them now in our greenhouſes.]

2. This differs from the preceding only in having the leaflets entire and all equal in ſize. [Alſtroemer remarks, that the fructification is quite the ſame as in the other:—Fabricius, that the ſtamens are from eight to eleven in number.—Native of Braſil and Peru.]

PROPAGATION AND CULTURE.

This plant is propagated beſt by ſeeds, which muſt be procured from the countries where they naturally grow: theſe ſhould be ſown in pots filled with freſh earth, and plunged into a moderate hot-bed. If the ſeeds are good, the plants will appear in about five or ſix weeks: and if they are properly managed by admitting freſh air daily to them, according to the warmth of the ſeaſon, and are duly refreſhed with water, they will be fit to tranſplant in about five or ſix weeks after, when they ſhould be carefully turned out of the pots and their roots ſeparated: then they muſt be each planted in a ſmall pot filled with ſoft loamy earth, and plunged again into a moderate hot-bed, ſhading them from the ſun till they have taken freſh root; then they muſt be gradually inured to the open air, into which they ſhould be removed ſoon after, placing them in a ſheltered ſituation, where they may remain till autumn, but they muſt be removed into ſhelter before the firſt froſts, otherwiſe their tops will be killed, and thereby the plants are frequently deſtroyed.

Theſe plants being tender when young, require a little warmth in winter; but after two or three years growth, they will live in a good green-houſe, where, as they retain their leaves all the year, they will make a good variety. It may alſo be propagated by layers and cuttings; the layers ſhould be put down in the ſpring, and by the following ſpring they will be rooted; the cuttings ſhould be planted in april, which will put out roots in about two months, and may afterwards be treated as the ſeedling plants.

2. The ſecond ſort may be propagated in the ſame manner; but the young plants being much more tender, will require to be placed in a moderate ſtove for four or five winters, after which they may be kept in a good green-houſe, giving them little water in winter.

Culm round leafy, ſpikes panicled, glumes mucronate.

19. Schoenus capillaceus. *Hair-leaved Bog-ruſh.*
Lin. ſpec. ed. Willd. 1. 263. *Thunb. prodr.* 16.
Culm round leafy, ſpikes ſubracemed, glumes cuſped, leaves capillary.

20. Schoenus uſtulatus. *Burnt Bog-ruſh.*
Lin. ſyſt. 95. *Reich.* 1. 119. *Willd.* 1. 263. *mant.* 178. *Thunb. prodr.* 16. *Rottb. gram.* 63. *t.* 18. *f.* 1.
Culm round leafy, ſpikes pedunculed pendulous oblong awned.

21. Schoenus ſpicatus. *Spiked Bog-ruſh.*
Lin. ſpec. ed. Willd. 1. 264. *Thunb. prodr.* 16.
Culm round capillary, heads ſpiked involucred.

22. Schoenus Bobartiæ.
Lin. ſpec. ed. Willd. 1. 264. *Retz. obſ.* 4. 9.
Culm compreſſed, head terminating, involucre five-leaved.

23. Schoenus ſtellatus. *Starry Bog-ruſh.*
Lin. ſpec. ed. Willd. 1. 264. *Swartz prodr.* 19. *deſcr.* 102. *Lamarck encycl.* 1. 733. *Sloan. jam.* 1. 119. *t.* 78. *f.* 1. *Raii hiſt.* 3. 624.
Culm ſubtriquetrous, ſpikelets conglomerate, with a leafy involucre coloured at the baſe.

24. Schoenus bulboſus. *Bulbous Bog-ruſh.*
Lin. ſyſt. 95. *Reich.* 1. 120. *Willd.* 1. 264. *mant.* 178. *Thunb. prodr.* 16.
Scirpus capenſis. *Rottb. gram.* 53. *t.* 16. *f.* 3.
Culm round ſiliform, ſpikes racemed directed one way, involucres ſolitary.

25. Schoenus inanis.
Lin. ſpec. ed. Willd. 1. 265. *Thunb. prodr.* 16.
Culm round leafleſs, ſpikes panicled, glumes acute.

** *With a three-ſided culm.*

26. Schoenus cephalotes.
Lin. ſpec. ed. Willd. 1. 265. *Rottb. gram.* 61. *t.* 20.
Culm leafy three-ſided, involucre four-leaved, bent down, head oblong terminating.

27. Schoenus cyperoides.
Lin. ſpec. ed. Willd. 1. 265. *Swartz prodr.* 19. *deſcr.* 110.
Culm three-ſided leafy, umbel terminating, ſpikelets glomerate.

28. Schoenus

Lin. ſpec. ed. Willd. 1. 268. *Swartz prodr.* 20. *deſcr.* 112. *icon.* 1. 7. *t.* 6.
Culm three-ſided naked filiform, ſpikelets terminating ſubfaſcicled ſeſſile, with a leaflet beneath equalling the ſpike.

41. Schoenus capillaris.
Lin. ſpec. ed. Willd. 1. 268. *Swartz prodr.* 20. *deſcr.* 106.
Culm three-ſided naked capillary, leaves capillary, ſpikelets faſcicled reflex involucred, involucret two-leaved.

DESCRIPTIONS, &c.

1. Root perennial. Culm three or four feet high, ſmooth and even, leafy, branched at top. Leaves linear-lanceolate, very long, acuminate, ſheathing at the baſe, entire, very ſharply ſerrulate along the edge and keel. Flowers ferruginous, in terminating and lateral corymbs, with ſheathing alternate bractes [e]. Glumes ovate-acuminate. Stigma trifid. Capſule ſubtriquetrous, mucronate, with a roundiſh ſeed [f].—According to Scheuchzer, this ſpecies has only two ſtamens.

Native of Europe and Africa, in fens and ditches. In the moors near Cambridge, the Iſle of Ely, and the great level of the fens. On St. Faith's Newton bogs near Norwich, and Ellingham fen in Norfolk. By the Thame at Dorſthill near Tamworth, Warwickſhire. By the ſea ſide between Penſance and Marketjeu, Cornwall. Hell-kettles near Darlington. In a large pool called Cars y Crom-Llyn, between Breton-ferry and Swanſea, &c. It is ſo common in the Iſle of Ely, &c. that it is brought up to Cambridge for lighting fires and heating ovens. In the fen towns it is frequently uſed inſtead of ſtraw for thatching; and in pools often grows in ſuch quantities as to form floating iſlands.

2. Native of Guinea.

3. Root perennial, creeping. Leaves very many, radical, collected into a bundle, very long, rugged at the edge, neither fleſhy nor flat. Culm firm, even, thicker and much ſhorter than the leaves. Involucre three-leaved, like the leaves but ſhorter: within this there are alſo three other leaflets ſtill ſhorter. Spikes very many, ſeſſile and forming a head, ſharpiſh, imbricate with ovate concave acute ſcales. Filaments three, linear. Germ obovate. Style ſingle. Stigmas three, oblong [g].

Native of the South of France, Spain, Italy, Barbary, Smyrna, on ſandy ſea coaſts.

4. Native of Guinea.

5, 6, 7. Natives of the Cape of Good Hope.

8. This has the appearance of *Scirpus paluſtris*. Radical leaves abundant, crowded, filiform, channelled on the inner ſide, having a wide white lateral membrane at the baſe. Culm naked, ſtriated, without any knot, a ſpan high. Spike terminating, cylindrical, an inch long; with lanceolate acuminate ſcales, the lower ones membranaceous. Stamens three. Styles three [h].

Native of the Eaſt Indies and the Cape of Good Hope.

9. Root perennial. Culm a foot high, quite ſingle, ſmooth. Leaves linear, half-round, ſomewhat rugged, widening at the baſe, brown, ſhining, thinner at the edge, ſheathing, ſhorter than the culm. Head roundiſh or ovate, compoſed of ſeveral ſpikelets, which are blackiſh-brown and ſhining. Involucre double, membranaceous; the inner one very ſhort; the outer ending in a leafy ſtraight point, three times as high as the head [i].

The numerous leaves form a thick tuft compoſed of ſmall bundles, each bundle covered with many broad ſcales of a blackiſh brown colour [k]. The ſpikeſtalk is flexuoſe; and the ſeeds are roundiſh, approaching to three-ſided, of a pearly luſtre [l]. Each ſeed lies within the correſponding curvature of the ſpikeſtalk [m].

Native of Europe and Barbary, in bogs and marſhes. In England not uncommon; flowering in june.

[e] Smith. [f] Relhan. [g] Linn. ſyſt. [h] Linn. mant. [i] Smith. [k] Linn. [l] Haller. [m] Stokes in Withering.

Digitized by Google

10. Root perennial, fibrous, a little creeping. Culm half a foot high, roundiſh a little flatted on one ſide, ſmooth, ſtriated, with a ſingle ſheathing leaf at the baſe, the reſt naked. Leaves almoſt all radical, alternate, ſhorter than the culm, linear, flat, keeled with the dorſal nerve, ſomewhat rugged at the edge. Spike terminating, almoſt upright, of a ſhining brown colour, compoſed of from five to twelve diſtich ſpikelets, the loweſt more remote from each other. Bracte ſolitary, leafy, with a triangular ſharpiſh top, roughiſh along the edges, moſtly longer than the ſpike. Flowers hermaphrodite. Seed ſurrounded with ſix rough briſtles at the baſe; which is alſo the caſe in Sc. glomeratus, an American ſpecies: hence they have both a great affinity to *Eriophorum*, in their character [n].—The two-rowed ſpike, ſays Dr. Withering, would almoſt induce one to refer *Sc. compreſſus* to the genus *Cyperus*, did not a more accurate examination ſupport its preſent arrangement.

Linneus has placed this among the ſpecies with a three-ſided culm; and Leers remarks, that although it is round and ſomewhat flattened, yet that below the ſpike it is triquetrous.

Native of Europe, in bogs. On Hinton moor, and between Little Shelford and Whittlesford in Cambridgeſhire. Near Darſingham-Bath, Norfolk. Chiſelhurſt in Kent. Basford Scottum, Nottinghamſhire. Not uncommon in other counties of England: flowering in july [n].

11. This is very nearly allied to *Sc. nigricans*, but it is ſix times ſhorter and narrower. Head ferruginous as in that, but compoſed of a double ſpike, and hence very narrow. Each of theſe ſpikes conſiſts of two flowers, very like thoſe of *nigricans*. The univerſal involucre is a two-valved ferruginous glume, the outer or larger valve mucronate, exactly the length of the whole ſpike, but the ſmaller valve is far ſhorter [o].—Native of Gothland.

Linneus himſelf confounded this with the next ſpecies. Our Engliſh botaniſts were miſtaken about it, till Dr. Smith ſet them right in his *Flora Britannica*. It has not been found in England: but whether the *ferrugineus* of Germany and Dauphiné be the ſame with that of Sweden, I am not able to determine. Villars compares it with *nigricans*, and ſays it is not ſo high, that the leaves are ſmaller, and one of them embraces the ſtem: that the ſpike is blacker, and in a manner ſeparate, more ſenſibly, into two or three lobes; the two leaves which ſupport it are ſhorter than the ſpike.

12. Root perennial, creeping, horizontal. Culm from four to ſix inches high, ſeldom higher, quite round, ſtriated, ſmooth, naked except at the baſe, where it has two ſhort leaves. Leaves half-round, even, channelled above, not keeled on the back, widening at the baſe, membranaceous, ſheathing: the radical leaves equalling the culm, twice as long as the ſtem-leaves. Spike terminating, ſhining brown, compoſed of five or ſix diſtich, approximating ſpikelets, with a ſubtriangular rachis. Bracte ſolitary, leafy, blunt, channelled, even, ſcarcely equalling the ſpike, but commonly much ſhorter, and ſometimes there is none. Spikelets uſually two-flowered, with the glumes ſwelling a little, even not ſtriated. Anthers linear, ſtanding out. Stigmas revolute. Seed briſtly at the baſe. Hudſon and Solander (from Yalden's manuſcript deſcription) have aſcribed to it a double row of glumes, under the name of calyx and corolla, which perhaps are the *glumæ congeſtæ* of Linneus.—Yalden obſerved two ſtigmas; Hudſon three.

Native of Scotland in marſhes: doubtful if in Weſtmoreland.—Iſles of Mull and Skye. Dunglas Caſtle. It flowers in july [p].

Lightfoot has figured it, very indifferently, as a variety of *Sch. compreſſus*.
